Many studies have looked at the relative success of different types of litigants (Kritzer and Silbey, 2003), and while the majority of studies have found that repeat players are more successful than one-shot players, the patterns reveal major complications. First, the largest gaps tend to come not between repeat players and one-shot players but between government litigants and nongovernmental litigants (Kritzer, 2003). Second, few researchers ask the question of whether one-shotters are better off with or without litigation as a means of dispute resolution; that is, litigation must be assessed not just internally but externally vis-à-vis its alternatives. For example, are persons injured through medical negligence better off using litigation as the means of redress, relying upon the good will of medical providers, or using a system of insurance that provides for medical expenses, loss of wages, and so forth?

In the United States, there has been substantial research on the outcomes of civil trials, particularly those trials decided by juries (Vidmar and Hans, 2007: pp. 267–338; Daniels and Martin, 1995; Seabury et al., 2004; Litan, 1993). Some of these studies focus on civil cases generally, while others focus on single areas such as medical malpractice (Vidmar, 1995) or product liability (Viscusi, 1986). Typically, these studies show a large proportion of verdicts or decisions involving modest amounts of money, but with a distribution showing an extreme tail consisting of a small number of very large verdicts (Cohen, 2004, 2005a, 2009; Langton and Cohen, 2008). Although over the broad range of cases plaintiffs win about half of the time and defendants win about half of the time (Priest and Klein, 1984), the studies also show a range of plaintiff success depending on the nature of the case, reflecting in part whether the uncertainty is over liability or the amount of damages (Wittman, 1985; Gross and Syverud, 1991).

One specialized theme has been the frequency and nature of punitive (exemplary) damage awards. Research consistently shows that such awards are infrequent, that they tend to be relatively modest, and that there is a strong correlation between compensatory damages and punitive damages when the latter are awarded (Eisenberg et al., 2002; Vidmar and Holman, 2010). Variability in punitive damage awards is greatest for cases with small compensatory awards (Eisenberg et al., 2010). Moreover, the likelihood of a punitive damage award varies depending on the type of case, with such awards most

likely in intentional torts and financial injury cases (Cohen, 2005b; Peterson et al., 1987: pp. 10–12).

Research looking at decisions of American trial judges vis-à-vis questions such as liability and damages is much less common. Research there shows that judges are more likely to find for the plaintiff, although the typical judge's award is about 20% less than the typical jury's (Cohen, 2009; Langton and Cohen, 2008; Clermont and Eisenberg, 1992; Kalven and Zeisel, 1971: pp. 63–65). A danger in all of these comparisons of decisions by judges and decisions by juries is that the cases decided by judges and juries are probably not comparable, because litigants themselves choose between the two types of trials.

Another line of research in the United States focuses on the substantive decisions of judges in civil cases (Carp and Rowland, 1983; Rowland and Carp, 1996; Epstein and Rowland, 1991). This research typically relies upon examination of published decisions by federal trial judges, and distinguishes between decisions labeled as 'liberal' and those labeled 'conservative' (using contemporary American notions of this continuum). The core results of the research demonstrate that there are measurable differences in outcomes depending on whether judges are identified with the Republican or Democratic parties based on either their own affiliation prior to appointment or the affiliation of the President who appointed them. One recognized problem with this research is that published decisions differ from the full population of decisions made by federal district judges in civil cases (Siegelman and Donohue, 1990; Olson, 1989), and results differ when unpublished decisions are included in the analysis, reducing or eliminating the relationship between decisions and partisanship (Ashenfelter et al., 1995).

While substantial attention has focused on formal adjudication by judges and juries, less attention has been directed at the outcomes of cases resolved short of adjudication. Part of the reason for this is that determining outcomes is more difficult because they are not part of the public records. A number of empirical studies (Genn, 1988; Kritzer, 1991a; Hyman et al., 1995; Fenn and Rickman, 1997; Swanson and Mason, 1998) have focused on the settlement process, both in the United States and elsewhere, generally showing that economic considerations (likelihood of success, who is bearing costs, the magnitude of costs both absolutely and relative to stakes) combined with risk preference are central to understanding settlement. Simply put, cases will tend to settle when the plaintiffs net expected gain (recovery discounted by probability of success *minus* expected costs) is less than or equal to the defendants' expected loss (payout discounted by probability of plaintiff success *plus* costs). When stakes are relatively small, this is almost always true (Kritzer, 1991a), and it is frequently true for larger cases even when there is substantial disagreement about the likely outcome. It is less clear to what degree the intervention of court officials can influence the settlement process, in no small part because such a large proportion of cases settle regardless.

Litigation Reform

How to improve the litigation process is a perennial issue (Zuckerman, 1999; Reda, 2012), and a final body of research deals with litigation reform. Although the term 'reform' suggests improvements, whether the changes proposed or implemented constitute improvements is a matter of debate. 'Reform' is used here to refer to change brought about through legislative or administrative action rather than changes resulting from decisions by courts in particular cases. One thread examines the politics of litigation reform including changes that create new opportunities for litigation (Daniels and Martin, 1995; Haltom and McCann, 2004; Burke, 2002; Farhang, 2010).

A second thread of research provides empirically based assessments of some aspect of the litigation system in order to determine what changes might be called for. In England, there have been a series of procedural reforms in recent years. In the mid-1980s, the then Lord Chancellor's Department commissioned a series of studies for what was called the Civil Justice Review. In the mid-1990s, Master of the Rolls, Lord Harry Woolf, undertook a review of the existing civil procedure rules and commissioned a study of litigation costs (Genn, 1996). Most recently, Lord Rupert Jackson of the English Court of Appeal conducted a review of cost-related rules, and again commissioned some empirical research (see the References for the link to the website with materials from Lord Jackson's inquiry).

A third thread of research has examined the impact of various reforms. In the UK, several studies have sought to assess the impact of the Woolf reforms (Fenn et al., 2009; Goriely et al., 2002; Zander, 2009); a second line of UK research has examined the impact of changes to cost and funding rules (Fenn and Rickman, 2011), and whether those changes have encouraged the development of what critics have termed a 'compensation culture' (Moorhead, 2010; Hand, 2010; Morris, 2007; Lewis et al., 2006). In the United States, there has been extensive research seeking to assess the impact of various changes regarding the handling of medical malpractice claims (Hyman et al., 2009; Daniels and Martin, 2010; Studdert et al., 2004; Sharkey, 2005; Pace et al., 2004; Avraham, 2007) as well as research on the impact of tort reform more generally (Eisenberg, forthcoming). One major US study sought to assess the impact of the federal Civil Justice Reform Act, which included the introduction of a variety of procedural changes with an emphasis on increased use of intensive case management (Kakalik et al., 1996).

A final thread of research linked to litigation reform considers the rise of alternative dispute resolution either as a part of the litigation process (e.g., the use of mediation in aid of settlement) or as a replacement for court-based litigation (Genn, 2010: pp. 78–125). Arbitration has a long history but has come to particular prominence in recent years as a means of dealing with everything from large complex international commercial disputes (Dezalay and Garth, 1996) to routine consumer problems (Drahozal and Zyontz, 2010, 2011; Eisenberg et al., 2008) and a range of issues in between (Gross and Black, 2009; Choi and Eisenberg, 2010; Yoon, 2004). Mediation has become extremely popular in recent years, both in the United States and elsewhere, and a substantial body of research concerning mediation now exists (Wissler, 2002; Relis, 2009; Genn et al., 2007; Bogoch and Kaddari, 2007).

Abstract

Karl Llewellyn was the most important figure in American Legal Realism and one of the most influential figures in Anglo-American law of the twentieth century. After some attention to basic biographical facts (education at Yale, time in Germany influence of 'free law' movement, professorships at Columbia and Chicago, role in drafting the Uniform Commercial Code), the article will focus on his major jurisprudential claims concerning the indeterminacy of legal reasoning, and the role of 'situation-types' and un-codified norms in judicial decision-making. The influence of these jurisprudential claims on his seminal work in commercial law will then be explored. Finally, some attention will be given to the influence and reception of his work in analytic jurisprudence, law and economics, and Critical Legal Studies

Biography

Karl Nickerson Llewellyn was born in Seattle, Washington, on 22 May 1893, though the family soon moved to Brooklyn, New York. At age 16, he went to Germany to study for 2 years, before entering Yale College in 1911. When World War I broke out, he was studying in Paris. Staunchly Germanophilic, he joined up with the 78th Prussian Infantry, was wounded later in 1914, and subsequently received the Iron Cross! Returning to Yale, he completed his undergraduate studies and enrolled in Yale Law School, from which he graduated in 1918. Wartime absences of faculty and students led Llewellyn to stay on at Yale for 1918–19 as editor-in-chief of the *Yale Law Journal* and as a part-time instructor teaching, due to curricular needs, commercial law – the field in which he would later become the most influential American figure of the twentieth century. He began working as a lawyer for a New York City bank in 1920, soon joining the prestigious corporate law firm of Shearman and Sterling. He joined the Yale faculty in 1922, moving to Columbia Law School in 1925; Columbia was then a fertile ground of the new 'Legal Realism,' a movement in which Llewellyn soon emerged as the major figure. He taught at Columbia until 1951, though he spent the academic year 1928–29 once again in Germany, as a visiting professor at Leipzig. During this time, he became better acquainted with the German 'free law' movement, which influenced Llewellyn's conception of Legal Realism. In the 1930s, he worked with an anthropologist doing field-work on American Indian law, as well as producing voluminous scholarship in commercial law. From the 1940s until his death, he made his seminal contributions to the Uniform Commercial Code. He moved to the University of Chicago Law School in 1951, which also hired his second wife, Soia Mentschikoff, herself an accomplished legal scholar. He spent the remainder of his career at Chicago, where he died of a heart attack on 13 February 1962.

Llewellyn and American Legal Realism

Llewellyn was the most important and famous figure associated with the American Legal Realism of the 1920s and 1930s, a movement that transformed the way both academics and lawyers thought about law. The Realists argued against the dominant 'mechanical jurisprudence' or 'formalism' of the day, which held that judges decide cases on the basis of distinctively *legal* rules and reasons, which justify a unique result in every case. The Realists argued, instead, that a careful look at how judges *really* decide cases reveals that they decide not primarily because of law, but based on their sense of what would be 'fair' on the facts of the case. Legal rules and reasons figure simply as post-hoc rationalizations for decisions reached on the basis of nonlegal considerations.

Legal Indeterminacy

The Realists argued that the law was 'indeterminate.' By this, they meant that the available class of legitimate legal reasons did not *justify* a unique decision, especially in those cases that reached the stage of appellate review. Llewellyn argued for indeterminacy based on the existence of conflicting, but equally legitimate, canons of interpretation for precedents, and statutes. So, for example, courts had endorsed *both* the principle of statutory construction that, 'A statute cannot go beyond its text,' but also the principle that 'To effect its purpose a statute must be implemented beyond its text' (Llewellyn, 1950: p. 401). But if a court could properly appeal to either canon when faced with a question of statutory interpretation, then the 'methods' of legal reasoning (including principles of statutory construction) would justify at least two different interpretations of the meaning of the statute. In that case, the question for the Realists was: why did the judge reach that result, given that law and legal reasons did not require him to do so? Llewellyn (1930) made a similar argument about the conflicting, but equally legitimate, ways of interpreting precedent, which he called the 'strict' and 'loose' views of precedent. According to Llewellyn, a judge almost always had the latitude to characterize the decision of a prior case in a highly fact-specific way, so as to distinguish it from the present case, or to characterize its holding in a way that abstracted from the specific facts of the earlier case, so as to make it binding in the present case. Thus, a precedent never really constrained a judge in a later case, because he could construe it 'strictly' to distinguish it, or 'loosely' to treat it as binding.

Two Branches of Realism

All the Realists agreed that the law and legal reasons are often indeterminate, so that the best explanation for why judges decide as they do must look beyond the law itself. In particular, all the Realists endorsed the following 'core claim': in deciding cases, judges respond primarily to the stimulus of the facts of the case, rather than to legal rules and reasons.

There was, however, a division among Realists over the question of how to explain why judges respond to the underlying facts of the case as they do. The 'Sociological' Wing of Realism – represented by Llewellyn (1930, 1960, 1962) – thought that judicial decisions fell into *predictable* patterns (though *not*, of course, the patterns one would predict just by looking at the existing rules of law). From this fact, these Realists inferred that various 'social' forces must operate upon judges to force them to respond to facts in similar, and predictable, ways. These social forces might include the economic background of the judges and their professional socialization experiences. It was these factors, rather than rules of law, that account for decisions and determine the responses judges have to the underlying facts of the case.

Llewellyn's focus was on the professional socialization and background of judges that would lead them to be sensitive to the norms of ordinary commercial practice. Focussing primarily on commercial law disputes, Llewellyn argued that what judges really do in these cases is try to enforce the uncodified but prevailing norms from the commercial culture in which the dispute arose. Llewellyn (1960: pp. 122–124) gave this famous example: a series of New York cases applied the rule that a buyer who rejects the seller's shipment by formally stating his objections thereby waives all other objections. Llewellyn notes that the rule seems to have been applied rather harshly in the NY cases, since either the buyers may not have known at the time of rejection of other defects or the seller could not have cured the defects anyway. A careful study of the underlying facts, however, revealed that in each case where the rule seems to have been harshly applied what had *really* happened was that the market had gone sour and the buyer was looking to escape the contract. The judge, being 'sensitive to commerce or to decency' (1960: p. 124) applies the unrelated rule about rejection to frustrate the buyer's attempt to escape the contract. Thus, the commercial norm – buyers ought to honor their commitments even under changed market conditions – is enforced by the courts through a seemingly harsh application of an unrelated rule concerning rejection. It is these 'background facts, those of mercantile practice, those of the situation-type' (1960: p. 126) which determine the course of decision.

Llewellyn's seminal work on the Uniform Commercial Code was informed by his Realist perspective (cf White, 1994). For example, the Code imposes an obligation of 'good faith' in all contractual dealings, which is defined as requiring not only honesty but also 'the observance of reasonable commercial standards of fair dealing in the trade.' But for a judge, then, to enforce the rule requiring good faith is just for the judge to enforce the norms of commercial culture! The reliance of the Code throughout on norms of good faith and 'reasonableness' is a constant invitation to the judge to do what he would, on the Realist theory, be likely to do anyway: enforce the norms of the prevailing commercial practice.

The 'Idiosyncracy Wing' of Realism, by contrast – exemplified most prominently by Frank (1930) – claimed that what determines the judge's response to the facts of a particular case are idiosyncratic facts about the psychology of that individual. Thus, Frank notoriously asserted that 'the personality of the judge is the pivotal factor in law administration' (1930: p. 111). This view is hard to square though with lawyers' ability to predict rather well what judges will do (if they could not do that, litigators, at least, would be out of business). Despite its extreme nature and limited appeal to most Realists, Frank's view has come to dominate the current picture of Realism, to the extent that Llewellyn's far more typical 'sociological' approach is often neglected.

Impact and Current Importance

By calling attention to the role of nonlegal factors in judicial decision-making, Llewellyn and the Realists initiated the interdisciplinary turn in American legal education, and made clear the need for lawyers to draw on the social sciences in understanding the development of law and what judges do. Much contemporary political science literature on law and courts takes its inspiration from Realism by seeking to explain decisions not by reference to legal reasons (which are assumed to be indeterminate) but by reference to facts about the politics, background, and ideology of the judges (Cross, 1997). Recently, it has even been argued that Llewellyn's own approach to commercial law anticipated the now dominant economic analysis of the business law fields (Schwartz, 2000). This should hardly be surprising, though, since the economists seek to structure legal rules to maximize efficient outcomes, but efficiency is surely an important norm of all mercantile practice: thus, if judges enforce the norms of mercantile practice (as Llewellyn claims they do and should do), it will turn out that judges will try, among other things, to produce efficient outcomes.

Llewellyn's work on Native American law and dispute resolution practices (Llewellyn and Hoebel, 1941) remains an anthropological classic, while his introductory lectures to Columbia law students (Llewellyn, 1930) may lay claim to being the most widely read book on law by generations of American law students. While the Uniform Commercial Code (UCC), the single most influential piece of commercial law in the US, bears Llewellyn's imprimatur, it is often lamented in recent years that revisions to the UCC have moved it away from Llewellyn's original vision of a Code sensitive to actual commercial practice. Even so, the lawyers and scholars effecting these changes continually feel the need to grapple with Llewellyn's conception.

Within jurisprudence, Llewellyn's ideas have been subjected to extensive criticism by analytical philosophers (notably H.L.A. Hart), though more recently a philosophical defense has been mounted (Leiter, 1997). Among legal scholars, however, Llewellyn's ideas remain influential, both in scholarly movements (like 'Critical Legal Studies' and 'Law and Society') that emphasize law's indeterminacy and the need to look at extra-legal factors to explain law, but also in the work of judges, who now attend to the specific facts of cases (the 'situation-types' as Llewellyn called them) and general nonlegal policy considerations much more openly than before the triumph of Realism in American law.

Local Economic Development

Christian M Rogerson, University of Johannesburg, Johannesburg, South Africa

Abstract

Local Economic Development (LED) has emerged globally as a vital planning approach for local economies. The emergence and growing significance of LED planning approaches are inseparable from the changing world economy and especially the advance of globalization. The question of catalyzing LED planning initially emerged in Europe and spread to other advanced economies. The geographical diffusion of LED has occurred to late-developing economies in sub-Saharan Africa and Latin America. The relevance of this place-based approach to contemporary development planning in the global South is widely confirmed. New evidence demonstrates that the implementation of LED approaches can raise human development prospects in the global South.

Globalization is a vital driver for reconfiguring planning approaches toward local and regional development (Christensen and van der Ree, 2008; Rodriguez-Pose, 2008). Arguably, a major facet of globalization is the increasing pervasiveness of markets around the world (Christensen and van der Ree, 2008: 2). Even the most remote places must take steps to adjust to the increased competition that globalization brings (Pike et al., 2006). Amidst circumstances of global economic turmoil, localities are compelled to find new solutions to support local competitiveness as well as to create inclusive development (ILO, 2008). Indeed, local economies are affected more than ever before "by policies and processes formed at the supranational level, such as market liberalisation, expanding global production systems and the changing terms of trade" (ILO, 2006: 2). Overall, therefore, the advance of globalization accords Local Economic Development (LED) strategies "a bigger role to play in international development" (Rodriguez-Pose, 2008: 24). More particularly, LED "offers a means to counteract or take advantages of the forces of globalisation by maximising local potentials" (ILO, 2006: 2). In the reshaped landscape of development planning, LED emerges as a vital new planning focus particularly in the context of pervasive trends toward decentralization – the deliberate and planned transfer of resources away from central state institutions – and of shifting structures of government and governance (Rodriguez-Pose and Tijmstra, 2007; Christensen and van der Ree, 2008; Rodriguez-Pose and Tijmstra, 2009).

The Emergence of LED

The developmental challenges posed by globalization precipitated a serious rethink about the validity of former approaches to development planning. LED approaches are generally distinguished from the so-termed traditional development policies.

The differences between traditional development policies and LED are captured for five domains by Rodriguez-Pose (2001):

1. Whereas in traditional top-down approaches the decision on where to implement development strategies is taken by central government planners and developers, with little or no involvement of local actors, LED practices favor the promotion of development in all territories by using the economic potential and the competitive advantage of every space. The initiative to launch the development strategy is taken locally or with strong local support.
2. As a result of where and how the decisions are taken, traditional policies have been generally designed, managed, and implemented by ministries or central government agencies. The involvement of local actors in LED strategies implies, in contrast, a much greater degree of vertical and horizontal coordination of all the actors involved. Vertical coordination entails the synchronization of local, regional, national, and supranational or international institutions. Horizontal coordination comprises local public and private actors concerned with development issues.
3. The LED approach is territorial rather than sectoral. Traditional policies have tended to adopt a sectoral approach. The promotion of specific industrial sectors that contribute to generate economic dynamism has been one of the main objectives of traditional policies. By contrast, LED uses a territorial approach as a means of achieving economic development. The diagnosis of the economic, social, and institutional conditions of every territory and the identification of the local economic potential are the foundations upon which a local development strategy is constructed.
4. Closely allied to the sectoral approach of most traditional development policies is the development of large industrial projects that were expected to promote additional economic activity and generate the networks and value chains needed to achieve sustainable development. The problems of this type of practice encouraged LED practitioners to identify and use the economic development potential of each area and to stimulate the progressive adjustment of the local economic system to changing economic conditions (Rodriguez-Pose, 2001).
5. The two approaches are set apart by their ways of attracting economic activity. While traditional approaches often rely on a national government for financial support, incentive packages, and subsidies in order to attract and maintain economic activity, LED tends to shun such activities and concentrate on the improvement of basic conditions in the locality for the development and attraction of further economic activity (Rodriguez-Pose, 2001).

As pointed out by several observers, LED is a contested concept and several definitions exist for it. For Bartik (2003: 1), LED represents increases in a "local economy's capacity to create wealth for local residents". The World Bank (2003) considers the activity of LED is about local people working together to achieve sustainable economic growth that brings economic benefits and quality of life improvements for all in the community. From a perspective rooted in the global South, Helmsing and Egziabher (2005: 1) consider LED to be a process wherein development partnerships are initiated among local governments, NGOs, community-based groups, and the private sectors in order to manage existing resources, create employment, and stimulate the economy of a well-defined territory. Other analysts forward that in the absence of a clearly defined theoretical model LED strategies often resort to the essential features of the approach to specify their content (Rodriguez-Pose, 2001: 8). The ILO distinguishes four core features to characterize LED strategies, namely that they require participation and social dialogue; are anchored on a specific territory; entail mobilization of local resources and competitive advantages; and are locally owned and managed. These characteristics coalesce in a definition that LED is a "participatory development process that encourages partnership arrangements between the main private and public stakeholders of a defined territory, enabling the joint design and implementation of a common development strategy, by making use of the local resources and competitive advantage in a global context, with the final objective of creating decent jobs and stimulating economic activity" (ILO, 2006: 2).

Finally, the German International Development Agency (GIZ), which has been actively promoting LED approaches in the global South, holds a similar view while specifying that LED should "tackle market failures, remove bureaucratic obstacles for local businesses and strengthen the competitiveness of local firms" (Ruecker and Trah, 2007: 15). The GIZ also sees LED as an ongoing process and recognizes that "stimulating local economic growth will also involve systemic change at larger scales" (Meyer-Stamer, 2008: 1). Of critical importance is the notion of the 'systemic competitiveness of a territory', which is viewed as the capability of a locality to generate rising income levels and enhance local livelihoods (Meyer-Stamer, 2008: 7).

A scan of international experience reveals different approaches to LED as well as different entry points for starting an LED process. Arguably, LED offers an integrated, context-sensitive approach to development rather than a 'one-size-fits-all' solution. Specific LED strategies for mobilizing local economic potential include innovative interventions relating to inter alia, infrastructure, strengthening local small and medium enterprises (SMEs) and their skills; attraction of foreign direct investment; fostering territorial competitiveness; capacitating local institutions; improved management of the development process; as well as internalizing local resources (Rodriguez-Pose, 2008: 23). Likewise, the ILO (2008: 2) forwards that bringing together local governments, the private sector, and civil society in a search for the right LED formula facilitates "the community to build from the 'inside-out', capitalizing on local assets rather than from the 'outside-in' relying on external interventions" (ILO, 2008: 2). "What links different approaches together is the quest for making local economies robust and creating productive jobs and also the recognition that local or regional competitive advantage rests on local interactions, knowledge spillovers and institutional synergies" (Salazar-Xirinachs, 2008: v). Although LED embodies a clear economic focus, it is not simply about economic growth; rather it is geared ultimately toward attaining a sustainable development trajectory that reconciles often conflicting economic, social, and ecological issues and objectives (Ruecker and Trah, 2007: 15). For some observers, the key contemporary challenge facing LED is "how to make the most of local resources in a way that improves returns from global markets" (Christensen and van der Ree, 2008: 2).

Rodriguez-Pose (2001, 2008) identifies numerous economic and social advantages of LED strategies over those of traditional development programs. The social advantages are that LED strategies empower local societies and generate local dialogues. Until recently people living in many areas of the developing world had little say or control over economic activity occurring in their territory; now they are beginning to adopt a more proactive stance with respect to their own future. Another social benefit is that the preparation and implementation of LED strategies assist in making local institutions more transparent and accountable thereby contributing to developing civil society. The economic advantages of the approach of LED are, however, its most significant strengths (Rodriguez-Pose, 2001, 2008). As LED strategies seek to embed economic activity in a territory and make economic activity dependent on the specific economic conditions and comparative advantages of that place, they generate sustainable employment in enterprises more capable of withstanding changes in the global economic environment.

LED as a Place-Based Policy Intervention

LED policies are part of a broader suite of debates on the validity of so-termed place-based as opposed to 'spatially blind' policies. To a large extent, these debates have been precipitated by the appearance of the World Bank's (2009) *World Development Report*. The Report is highly critical of the heavy focus by certain policy makers in searching for 'spatially balanced development' (World Bank, 2009: 73). The World Bank Report offers the core message that economic development inevitably will be geographically uneven and that to introduce or continue with policies designed to spread out economic activities – spatially or across a national urban system – carries with it the inherent danger that economic growth may be discouraged or arrested (World Bank, 2009). This said, the Report asserts that "development can still be inclusive, in that even people who start their lives far away from economic opportunity can benefit from the growing concentration of wealth in a few places" (World Bank, 2009: xxi). The essential parameters for achieving inclusive development are spelled out as follows: "With good policies, the concentration of economic activity and the convergence of living standards can happen together. The challenge for governments is to allow – even encourage – 'unbalanced' economic growth, and yet ensure inclusive development. They can do this through economic integration – by bringing laggard and leading places closer in economic terms" (World Bank, 2009: 20). It is explained this integration can most

appropriately be undertaken "by unleashing the market forces of agglomeration, migration and specialization, not by fighting and opposing them" (World Bank, 2009: 21).

A vital question posed in the Report is whether governments should invest in people or places. The World Bank favors investments in "activities that produce the highest economic and social returns nationally" (World Bank, 2009: 231). World Bank advice is "in economically leading regions, to invest in durable, export-oriented activities aimed at increasing national growth whereas in lagging areas investments should be in people to poverty reduction" (World Bank, 2009: 231). The key message of the Report is the need to reframe policy debates away from a sole focus on spatial targeting and instead to promote a menu of policy instruments, which might include but will necessarily foreground spatial targeting, in the overarching search for economic integration.

The Report advocates *'spatially blind'* rather than spatially targeted policy interventions. The term 'institutions' is used as shorthand to embrace "all the policy instruments that are spatially blind" (World Bank, 2009: 38); it includes the "amenities that governments should provide to everyone, regardless of place". This is explained as embracing mechanisms for the universal delivery of "basic amenities such as the administration of justice, public security, the regulation of land, labor and capital markets, education and health and electricity, water and sanitation" (World Bank, 2009: 38). Spatially blind policies include "such national policies as the income tax system, intergovernmental fiscal relations, and the governance of land and housing markets as well as education, health care, basic water and sanitation" (World Bank, 2009: 240). By contrast to spatially targeted interventions, it is considered that spatially blind interventions involving universal and progressive income taxation, social security, and unemployment benefits 'work less noisily' (World Bank, 2009: 238). Moreover, "as the base of economic integration, such 'institutions' capture the benefits of spatial concentration of production and deliver convergence in living standards" (World Bank, 2009: 238).

The World Bank's advocacy of spatially blind policies as opposed to *place-based interventions* has created controversy. Among others, Turok (2013: 1) sees 'serious omissions and shortcomings' in the Report as a consequence of reducing the complexity of spatial development to a few simple distinctions. In addition, the Report evidences undue faith in the ability of market forces to reduce spatial inequalities and a "notable lack of faith in the capabilities of the State to stimulate and sustain economic development in lagging areas" (Turok, 2013: 6). For Garcilazo (2011: 466) also the case for place-based policy responses is clear. Although the largest cities contribute disproportionately to national and aggregate economies, the contributions of smaller cities and rural areas should not be overlooked. Accordingly, there is a need for a differentiated approach capable of unleashing the growth potential of these other regions and localities, which would be through place-based policy interventions (including LED). It is maintained therefore that place-based policies are 'best equipped' for the task of unleashing and maximizing the growth potential of all regions and localities (Garcilazo, 2011: 466).

Place-based interventions highlight the importance of place-to-place differences by considering the array of different contextual factors that can influence the potential returns of intervention (Barca et al., 2012). The underlying principle is that tackling underutilized potential and reducing social exclusion may be best achieved by using place-based policy to maximize the growth potential of each locality or region (Tomaney et al., 2011: 626). Barca et al. (2012) note that a place-based development policy builds on local knowledge, incorporates local values, and mobilizes partnerships across different levels of governance, which strengthens institutions (Barca et al., 2012: 147). The success of place-based policies demands that local (and regional) actors be galvanized to assume a constructive and leading role in policy but also that these actors work with others from more distant locales to design and deliver the policies.

Overall, therefore, in a fluid global context of financial crisis, food crises, and the rising political and economic significance of (parts) the global South, place-based solutions are seen as better suited to current and future circumstances than the spatially blind approach advocated by the World Bank (Tomaney et al., 2010, 2011). In particular, support for place-based approaches promotes not just economic growth but also reduced inequality and lower territorial polarization (Tomaney et al., 2011: 626–627).

The Geographical Spread of LED

The origins of modern LED practices trace back to the 1960s. Pressures to stimulate LED came from at least two main directions: the persistence of uneven and inequitable economic outcomes and concerns about the dearth of local investment in certain regions (Le Heron, 2009: 93). Although interest in LED first emerged in Western Europe and North America, during the 1990s in particular LED ideas and practices spread from the global North to the global South (Nel and Rogerson, 2005; Rodriguez-Pose and Tijmstra, 2009).

Several recent writings affirm the continued global relevance, if not increased importance, of local (and regional) development policies in the context of the rapid unfolding of events that are reconfiguring the global economy (Rodriguez-Pose and Tijmstra, 2009; Pike et al., 2011). A combination of seismic international events has altered the prospects for local and regional developments (Tomaney et al., 2011: 618). The global financial crisis that unfolded after 2007 has profoundly influenced the prospects for LED internationally (Tomaney et al., 2011). Other critical considerations are the growing significance and expansion of South–South trade with the formation of new economic blocs, such as Brazil, Russia, India, China, and South Africa (BRICS) and the mounting acknowledgment of the need to implement adaption and mitigation strategies in relation to the consequences of global climate change. Furthermore, changes in international financial regulations, investment flows, and trade are also anticipated to affect local development futures (Tomaney et al., 2010: 773). Other issues relevant to LED futures include the management of natural resources, climate change, food security considerations, and access to water and energy.

In the contemporary, global economy localities are increasingly viewed as pivotal sites of competitiveness. Most importantly, the works of Pike et al. (2006), Rodriguez-Pose (2008), and Crescenzi and Rodriguez-Pose (2011) show that

in a world of rapidly reorganizing economic activity, the ability of the 'top-down' policy paradigm to deal with these challenges is called into question. Instead, as argued by Crescenzi and Rodriguez-Pose (2011: 2), the category of 'bottom-up' local development policies have been mobilized to address this operational vacuum. Bottom-up policies can have an impact on the natural economic potential, which is viewed as growing from within localities (Pike et al., 2006: 155). Through empowering local actors and making them directly responsible for the design of their own collective response to the challenges of the changing global economy, bottom-up policies often are considered effective alternative pathways to those offered by traditional approaches to development (Crescenzi and Rodriguez-Pose, 2011: 2).

Overall, LED policies are considered to represent a critical response to the territorial challenges produced by globalization, a response that is relevant to both advanced and developing countries. This said, the greatest challenges for LED are in the global South, in particular Latin America and sub-Saharan Africa. In poor and late-developing countries, including those in Latin America and sub-Saharan Africa, the recent emergence of local development policies represents a similar response to that which occurred in the global North, namely "an answer on behalf of localities and territories to the challenges of poverty, productive restructuring and increased competition" (Vazquez-Barquero, 2011: 509). At the local scale in Latin America, experiments in several countries have been undertaken with the innovation of new radical local development interventions to directly address high local levels of poverty, informality, inequality, and development (Bateman et al., 2011). Colombia is seen as in the vanguard of this new movement starting with its capital city of Bogota. Nevertheless, Bateman et al. (2011: 1–2) identify the city of Medellin as the "pioneer in developing a new Post-Washington consensus local economic policy". At its core is the notion that follows that of the successful industrial districts in Western Europe that subnational levels of government can, and should, be proactive in building the institutional and organizational infrastructures required for the successful emergence, expansion, and upgrading of growth-oriented micro-, small, and medium enterprises (Bateman et al., 2011: 2). Of special importance is that in Medellin the local developmental state model was anchored upon what is described as "creative forms of local state ownership and control of key enterprises" (Bateman et al., 2011: 2). In Medellin, financing was secured through local state ownership of key enterprises and assets that produced a revenue flow and specifically involved city ownership and effective management of the main energy company, which was mandated to channel 30% of its net annual profit to the city budget. This financial bounty allowed the city the fiscal space to engage in economic and social development areas beyond those that otherwise have been possible. Two examples are the establishment of a propoor transport system that allows the poor to work in more distant areas as well as for informal enterprises to sell their goods through improved access to the city center and the initiation of a network of publicly funded business support centers located in the city's poorest areas and targeted to support business development by the poor with free business support services and technical advice to aspirant entrepreneurs as well as a microcredit facility.

Bateman et al. (2011) have argued that this propoor model of LED from Medellin offers significant lessons for Latin America and elsewhere in relation to the potential and pitfalls of proactive LED policy operating in extremely marginal communities. The intervention support for microenterprises resulted in increasing the number and quality of microenterprises operating in the poorest communities creating an equality of opportunity for establishing a functioning business. One shortcoming has been that policy support so far has mainly been upon microenterprise as opposed to linking to issues of higher productivity SMEs, which is advocated in the concept of productive development policies. Nevertheless, the Medellin case is viewed as a promising demonstration of the local developmental state and a positive response to what are considered the failures of neoliberalism. Improved intervention is necessary, however, in particular with regard to improving transfer of technology, innovation, and knowledge to enhance the productivity of small- and medium-sized businesses (as opposed to microenterprises) (Bateman et al., 2011).

Across sub-Saharan Africa the rising importance of LED is signaled by the activities of the United Cities and Local Governments of Africa (UCLGA) (Swinburn and Yatta, 2006). The UCLGA is the united voice and representative of local government in Africa, an association of local governments, individuals, and entities interested in African local government. As part of UCLGA's mission of "Building African Unity from within and Driving Development through the Grass Roots", LED is identified as one of six key priority areas for action for the period 2006–15. By identifying LED as a priority for urban Africa, Swinburn and Yatta (2006) concede national-level macroeconomic policies no longer are sufficient for attaining sustainable broad-based economic growth. Moreover, as globalization diminishes the powers of the nation state in Africa and correspondingly underlines the role of localities and wider city regions as drivers of national growth, traditional sectoral supply side development strategies are not achieving hoped-for outcomes (Swinburn and Yatta, 2006). Within Africa, the South African case is usually highlighted as exceptional for the extensive devolution and decentralization of powers that have taken place (Nel and Rogerson, 2005; Rodriguez-Pose and Tijmstra, 2007; Rogerson and Rogerson, 2010). Certainly, within Africa, planning for LED in South Africa is the most advanced and longest established and since the 1994 democratic transition, LED has been elevated from isolated local development intervention, mainly in its leading cities, to an obligatory mandate for all local authorities (Nel and Rogerson, 2005). The well-documented South African experience offers a wealth of potential lessons for late-developing countries variously concerning the merits of progrowth vs propoor approaches, institutional arrangements, and potential roles of local government for energizing LED (Rogerson, 2008, 2010; Rogerson and Rogerson, 2010).

Reaffirming the Case for LED

Although a range of international development organizations has recommended LED strategies for the past two decades, monitoring and evaluating the success/failure of such interventions remains problematic. Twenty years ago Clarke and

Gaile (1992: 193) pointed out efforts so far undertaken to evaluate LED policy had been "a quagmire of good intentions and bad measures". The popular trend by LED analysts and practitioners has been to search out 'good practice' case studies. Rightly, Valler (2011: 569) points to the paucity of evidence regarding what constitutes success or failure of LED in particular localities. A major challenge in evaluating LED outcomes concerns assessment of what changes, if any, might have happened in the absence of LED interventions (Valler, 2011). On the whole, systematic monitoring of different LED strategies has received little attention (Rodriguez-Pose and Palavicini-Corona, 2013: 303). As a result, whether LED strategies truly change development outcomes in either the developed or the developing world remains in question.

The most powerful evidence from an evaluation of the impact of LED strategies is the recent work in Mexico by Rodriguez-Pose and Palavicini-Corona (2013). They conduct a quantitative analysis of 898 municipalities in Mexico to assess the impact – success or failure – of LED activities. They conclude that "pursuing or even thinking about LED strategies has paid off for local authorities in Mexico in the last two decades" (Rodriguez-Pose and Palavicini-Corona, 2013: 313). A major conclusion is perhaps that the "main difference remains between thinking and/or implementing one basic element of a LED strategy or doing nothing" with those municipalities doing nothing seen as "as a result, worse off in development terms" (Rodriguez-Pose and Palavicini-Corona, 2013: 313). This Mexican evidence suggests that the greatest impact on human development emerges through the design of a development plan, the implementation of capacity building measures, and the forging of new development links both within and beyond the municipality. Overall, this seminal study offers the first definitive confirmation that greater human development in the global South is possible through local development strategies.

Abstract

Absolute and relative location are fundamental geographic concepts. Absolute location facilitates the organization of geographic data and information for analysis and mapping. Relative location relationships such as inclusion, connectivity, direction, and distance are important to many real-world physical and human phenomena. This article reviews the geographic concepts of absolute and relative locations. This includes fundamental concepts of geographic space, describing absolute location through geographic referencing, and describing relative location through spatial relations.

Introduction

Location refers to a place within a system of places or *space* where an entity can exist. *Absolute location* defines that place with respect to all possible places within the space, typically using a referencing coordinate system. Examples include latitude and longitude or map coordinates. *Relative location* defines that place with respect to its connection, direction, or distance to other places, typically those occupied by other entities of interest. Examples include statements such as 'The road intersects the park,' 'Berlin is north of Vienna,' and 'My house is 3 km from the university.'

Absolute and relative location are central concepts in geography and geographic information science. Absolute location is a fundamental way of ordering information about physical and human properties of the Earth surface, both in the traditional format of paper maps as well as digital formats such as those found in geographic information system (GIS) software. Relative location is critical for everyday use of geographic concepts and information such as navigation, wayfinding, and other human behavior (Egenhofer and Mark, 1995; Freundshuh and Egenhofer, 1997). In addition, relative location conditions the physical and human phenomena at particular geographic locations; for example, neighborhoods that are proximal tend to have similar crime rates, and wind direction affects the risk of exposure to airborne toxins from a source. Relative location is central to *spatial analysis* or the quantitative measurement and analysis of phenomena based on relative location (Miller, 2004; Miller and Wentz, 2003).

Geographic Space

The concepts of space and location are highly general and not limited to geography and geographic information science. We can define a space by designating a set of objects and relations between these objects (Gatrell, 1983). Since this definition can encompass any structured collection of objects, it is too general to describe the spaces of interest in geography (Worboys and Duckham, 2004).

Geographic space or *geospace* is a type of space that represents some portion of the Earth's surface. A geospace consists of a set of *places* where attributes or objects can exist and a *spatial relation* measuring the separation between pairs of places. The set of locations can be *strictly bounded* or *countably bounded*. A strictly bounded set of locations is isomorphic to the set of integer numbers; this treats space as *discrete* or consisting of a distinct lattice of places. A countably bounded set of locations is isomorphic to the set of real numbers; this conceptualizes space as *continuous* or consisting of dense fabric of places. In practice, however, all spaces represented in digital computers are strictly bounded since these computers have finite resolution for representing numbers, including those describing places (Beguin and Thisse, 1979; Miller and Wentz, 2003).

A configuration of places supports the concept of *absolute location*. In geography, the configuration of places typically corresponds to a *plane* in low-dimensional space; examples include networks (one-dimensional space), map space (two dimensions), or natural space (three dimensions). Places can be referenced spatially using *Cartesian coordinates* or positions along defined axes representing the spatial dimensions. Equivalently, we can reference a place with respect to the axes' origin using *polar coordinates*. When representing large portions of the Earth's surface (such as continents), it is more natural to configure these places in *spherical* rather than planar space. In this case, we reference each place with respect to the sphere's center, poles, and a reference plane at the midpoint between the poles. If we give each place in a planar or spherical configuration of places a unique reference based on its position, we can refer to its position exactly or absolutely.

The concept of *relative location* requires defining a spatial relation that describes the separation among places in the system. A common spatial relation is *distance*: this describes the length of the shortest path between any pair of locations. The distance relation typically satisfies the *metric space* properties of *nonnegativity* (the distance between any two locations is never less than zero), *identity* (the distance of a location to itself is zero), symmetry (the distance between two locations is the same in either direction), and *triangular inequality* (the indirect distance between two locations is never smaller than the direct distance). A general distance function for planar space that satisfies these requirements is

$$d_p = \left[\sum_{k \in X} \left| x_i^k - x_j^k \right|^p \right]^{\frac{1}{p}}$$

where x_i^k is a k-dimensional vector describing the coordinates of location i and p is a parameter indicating the *distance norm*. Important special cases include $p = 2$: This corresponds to the Euclidean distance norm, with the shortest path corresponding to the straight-line segment between the two locations. Another special case occurs when $p = 1$: this corresponds to the so-called Manhattan metric where all segments of any path between two locations are parallel to the axes, similar to navigation of a gridiron road network. The distance norm parameter p can be any real number equal to or greater than one; values for p less than one means that the distance relations do not satisfy the triangular inequality and the space is no longer metric. The value of p can also be estimated from observed travel distances, including distances within transportation networks (Love et al., 1988).

A Euclidean distance norm is typical in geography and geographic information science: almost every paper or digital map assumes Euclidean distance. Euclidean distance as well as any distance norm also encompasses other relative location concepts such as *set-based* (inclusion vs exclusion in a set of locations), *topology* (connectivity), and *direction*. However, we can refer to these more primitive spatial Euclidean distance norm relations without requiring that distances satisfy the Euclidean or any other spatial metric; in fact, we do not need the concept of distance at all to describe set-based, topological, and directional relations (Worboys and Duckham, 2004). We will describe these relative location concepts more fully below.

In spherical space, the shortest paths between any two locations is the smaller arc of the *great circle* passing through the locations, where a great circle is a circle on the surface of a sphere with its center coinciding with the center of the sphere (Love et al., 1988). Spherical distance functions can obey the metric space properties identified above (nonnegativity, identity, symmetry, and triangle inequality).

Describing Absolute Location: Geographic Referencing

Describing absolute location on the Earth's surface involves five issues: they are geodetic datum, map projection, coordinate system, map scale, and precision/accuracy (Campbell, 2000). The *geodetic datum* is a model of the Earth's shape. Although we often conceptualize the Earth as a sphere, an ellipsoid is a better representation as rotation causes the Earth to be slightly flattened. An even better representation is a *geoid*: this is an ellipsoid-like model of the Earth that considers its irregular gravity surface. A range of datums exists, both global and local; these differ with respect to their description of the Earth. One common datum is the World Geodetic System 1984 (WGS 84); this datum is geocentered and supports the global positioning system.

It is possible to use geodetic datum coordinates directly; an example is the latitude and longitude systems. However, we often transform these measurements to a plane for ease of use in both paper and digital form. A *map projection* transforms locations on a curved surface to a flat plane. A map projection cannot simultaneously preserve all geometric properties such as area, angles, distances, and directions; therefore, one must choose which properties to preserve, thereby distorting the others. *Conformal* projections preserve angles; a well-known example is the Mercator projection. *Equal-area* projections preserve areas; an example is the Lambert projection. *Equidistant* projections maintain distance relation relative to a designated location; an example is conic projections.

Coordinate systems reference locations in geodetic (unprojected) or planar (projected) space. Most coordinate systems use the Cartesian coordinate system, although some land surveying maps use polar coordinates. The previously mentioned latitude and longitude system is a Cartesian coordinate system referring directly to the geodetic datum. Latitude expresses location relative to the equator while longitude expresses location relative to the Prime Meridian at Greenwich, U.K. A common planar coordinate system is the Universal Transverse Mercator system based on a type of Mercator projection.

Describing absolute location with respect to the Earth also involves a choice of *map scale*. Map scale is the ratio of map distance to ground distance. For example a 1:24 000 scale means 1 inch on the map is equivalent to 24 000 inches on the ground while a 1:100 000 scale means 1 inch on the map is equivalent to 100 000 inches on the ground. The smaller the ratio, the larger the map scale and the more detail can be represented on the map. However, larger map scales involve bigger data volumes.

Positional *precision and accuracy* are two distinct but related concepts. Precision refers to the resolution of the measurement, while accuracy refers to the degree to which the information on the map matches reality. Both precision and accuracy are functions of map scale, with larger map scales having higher precision and therefore higher potential (but not necessarily actual) accuracy. Map accuracy standards for horizontal and vertical errors are consequently related to map scale. For example, the US Federal government requires for maps larger than 1:20 000 to have not more than 10% of the points tested to have horizontal error of more than 1/30 inch measured using the map publication scale (USGS, 2006).

Describing Relative Location: Spatial Relations

Relative location describes places with respect to their inclusion, connection, direction, or distance to other places, typically those occupied by other entities of interest. There are four major classes of *spatial relations*: they are set-oriented, topological, directional, and distance relations (Worboys and Duckham, 2004). These are not mutually exclusive, but the ordering above indicates increasing sophistication and therefore inclusion. For example, set orientation by itself is the most primitive conceptualization and does not include richer spatial relations related to topology, direction, and distance. However, a space with metric distances also has implicit set-oriented, topological, and directional relations.

Set-oriented relations use set theory to conceptualize relative location. Each place is an element, and a set of places represents the geometric footprint of a spatial object such as a polygon. Based on this conceptualization, set theory operators such as intersection, union, difference, and complement can be used to characterize the relationship between different spatial sets.

Topological relations describe properties that do not vary under topological or 'rubber sheet' transformation of the space

(that is, continuous transformations that do not involve tearing or punching holes in the space). Topological relations focus on connectivity, interior, exterior, and boundary relationships between places. Potential topological relationships among spatial objects such as points, lines, and polygons are surprisingly rich and can differentiate among a wide range of configurations (Egenhofer and Franzosa, 1991).

We can classify *directional* relations between spatial objects based on the frame of reference. *Cardinal* directional relationships use an external reference frame, typically the directions north, south, east, and west. An example is the statement 'the university is north of the city center.' *Object-centered* directional relations use a designated object as a reference frame; an example is 'the park is behind the school.' *Ego-centric* directions use a viewer's perspective as a reference frame; an example is 'the restaurant is on the left.'

As discussed above, *distance* relations are fundamental to most conceptualizations of geographic space although it is a sophisticated spatial relation that encompasses other, more primitive relations. Distance is a straightforward concept when applied to individual places but more complicated when applied to spatially extensive collections of places such as lines, polylines, and polygons. Except for points, a distribution of distances exists between two spatial objects; summaries of this distribution include the minimum, maximum, average, and Hausdorff (maximum of the minimum) distances. Commercial GIS software typically uses the centroid-to-centroid distance between two spatial objects to approximate the average distance, but this approximation is less accurate as the objects become larger and closer together (Okabe and Miller, 1996).

Location Theory

Cees Gorter[†] **and Peter Nijkamp,** VU University, Amsterdam, The Netherlands

Abstract

This survey of location theory offers a brief overview of both traditional locational analysis and a modern orientation toward trade and growth theory. Decisions of households are also reviewed briefly, followed by a broader exposition of modern search theory and of the potential of the modern information and communication technology. Finally, it offers a survey of classical facilities location theory and an exposition of recent advances.

The 'Where' Question: Space Is Crucial

Geographical space is the action space of individuals, households and firms. Location and allocation are two sides of the same coin. This seemingly simple observation leads to a wealth of spatial – economic phenomena that are well covered in the recent literature (see Fischer and Nijkamp, 2013). Examples are housing and labor markets, regional growth disparities, spatial innovation and entrepreneurship conditions, urban agglomerations, industrial clusters, or energy and environmental resource scarcity. All such phenomena are critically determined by the location of human and industrial activity. There is an abundance of both conceptual and applied studies that address the above-mentioned spatial mapping of activities. The present contribution aims to highlight the essential elements of standard location theory.

Location theory is concerned with the intriguing question of where economic activity can be found. It addresses the geographic dimension of economic decisions and analyzes the behavior of firms and households. Thus the locus, the geographic place, is of prime interest in location analysis.

More specifically, the main question in location theory is what are the motives to choose a particular location and what are the geographic implications? Clearly, there is not a single, conclusive answer. A student who has just left the university will usually have different aims in mind when seeking a residence than will his parents who have just retired. Despite the variety of motives and goals, many factors are common to anyone seeking a residential location (such as affordability, accessibility, quality of life, etc.).

The same applies to business firms. An ice-cream vendor will not open a shop in a dead-end street, and a diamond seller will not opt for a location in an underground station. Both may have profit motives, but their decisions regarding where to locate may be totally different. Nevertheless, the actual location patterns of business firms reveal some similarities. The location patterns of households and firms are not random worldwide, but display many regularities. For instance, all over the world we find a population concentration and business concentration in river basin areas and delta areas, a phenomenon observed by Adam Smith more than 200 years ago. Many theoretical and methodological contributions on location analysis can be found in the recent *Handbook* by Fischer and Nijkamp (2013).

Location theory does not investigate the spatial point decision of only an individual actor (household, business firm), but looks also into the regularities (patterns, geographic structures) that emerge out of the decisions of many individual actors. Locational decisions are usually influenced by so-called externalities, which mean that the decisions made previously by a group of actors affect the current decisions of new market entrants. This explains why cities emerge as a spatial conglomerate of many individual actors seeking urbanization economies, or why industrial complexes arise as a consequence of agglomeration advantages (such as a joint use of infrastructure). Thus, location theory has both micro- and macro (collective or social) aspects; locational decisions are in the end usually interactive decisions. The importance of scale advantages in locational choices and the influence of distance friction costs have stimulated much research on spatial flows (often mentioned as spatial interaction models). In this context, the Newtonian gravity principle plays often a central role. Gravity models have been a key instrument in location-allocation analysis (see for a review Nijkamp, 2013).

Clearly, once a spatial pattern of economic activity has been realized, it will influence other patterns as well. Consumers tend to be attracted by the proximity of shopping facilities, business centers tend to orient themselves toward the presence of a critical mass of clients with a high purchasing power, etc. Thus, there is interactivity in location at the micro- and the meso-/macroscales. This spatial interactivity does not lead to a random spatial configuration, but to a regular – often hierarchical – organization of spatial systems. This is clearly reflected in central place theory, and in related statistical regularities described by the Zipf's Law (or its companion, the Gibrat's Law) (see also Reggiani and Nijkamp, 2014).

The next section offers a concise presentation of some highlights from traditional location theory, followed by an exposition of some modern developments. After a discussion of firms' location decisions, households' decisions will be looked at. The impact of the modern network economy and of information and communication technology (ICT) will be dealt with as well. This article concludes with some prospective remarks.

Conventional Wisdom on Location Decisions of Firms

Location theory forms a central element in regional economics and economic geography. Location and trade were regarded by the grandfather of economics, Adam Smith, as

[†] Deceased.

two interwoven phenomena: location influences trade flows and trade affects location decisions. In the history of economics a great variety of contributions on the nature, motives, and implications of the location of production can be found. We will offer only a few examples here from this rich history.

Location and land use in agricultural production was studied extensively by Von Thünen (1842), by using a simple profit maximization scheme for spatial product choices, as a function of revenues, product types, and transport costs. He was able to demonstrate the existence of a set of concentric rings of agricultural products, based on Ricardian comparative cost theory leading to product specialization. Von Thünen's rent theory has formed the basis for urban land rent theory, which has become a central focus in urban economics.

The location of industrial firms was investigated by Weber (1909) by looking for a cost minimizing location solution of a new firm on the basis of transport costs for resource inputs (and other material inputs) and for product outputs (to be shipped to the market). This intriguing and complex question was solved by Weber (1909) by using a triangular force field of input and output points, within which the optimal location has to be found.

The spatial concentration of economic activity in a city has also been studied intensively, starting from the work of Marshall (1925), who argued that agglomeration benefits are central for city formation. He referred to externalities which caused such benefits, in particular better information and skills, trade growth, specialized equipment, and availability of skilled labor.

The shift toward multiproduct economies and the spatial interrelationships between multiple products received due attention some 50 years ago in the context of the so-called central place theory, developed by Christaller (1933) and Lösch (1954). The basic idea is that the location of economic activity is subject to agglomeration advantages. As a consequence, economic activities are not spread randomly, but manifest themselves in clusters. Moreover, in the light of product diversity, price elasticity, and the existence of daily and nondaily goods, a spatial hierarchy is a logical outcome of a series of profit-maximizing location decisions of firms. This hierarchy means that a place with a certain ranking order also includes firms producing goods with a lower order. This theory has become a landmark in location theory and has had far-reaching implications for spatial planning.

In the postwar period, a wide range of new and refreshing contributions has also been offered, such as the growth pole theory, the cumulative causation model, and the forward–backward linkage view on regional development (see also Thisse et al., 1996).

The complexity of location decisions in a continuous space or in a discrete network configuration has also prompted a rich research field in the operations research discipline, where many attempts have been made to derive mathematically the optimal site of public facilities or private goods, especially in the context of a multiproduct location decision. It should be noted that in a discrete space with a finite number of location options the number of combinatorial possibilities may be formidable, so that rather advanced mathematical software has to be developed.

In the 1990s much attention was given to a rigorous analysis of the link between trade and locations, especially in the spirit of the monopolistic competition approach advocated by Krugman (1991). In this analysis, spatial accessibility does not only favor transport and trade, but geographical clustering is also positively influenced by a strong critical mass of local demand, by increasing returns to scale in the production sector and by a good transportation system in the area. In a later publication, Krugman (1995) has emphasized that locational factors and spatial interaction effects may be understood from the perspective of two main drivers, viz., agglomeration forces and distance friction costs. Such forces are the main determinants of the complex space-economy. This issue will be discussed in more detail in Section Location and Growth.

Location and Growth

Locational decisions are usually not stand-alone choices of a firm, but are part of a broader set of firm decisions, e.g., on market areas, marketing channels, technology to be used, image, etc. Against this background transport – and thus trade – plays an important role. This fact was recognized in the well-known Heckscher–Ohlin theory on international (or interregional) trade flows, where trade intensity between two countries is dependent on the comparative advantage of the use of factor inputs. Clearly, also the degree of homogeneity of products to be traded plays a role here. Based on the assumptions of monopolistic competition, Dixit and Stiglitz (1977) have tried to make the Heckscher–Ohlin theory more realistic, inter alia by allowing for product differentiation. In this way, both inter- and intraindustry trade flows and locational patterns can be analyzed. This integration of trade theory and location theory forms one of the main characteristics of modern growth and trade theory.

In this context there is also a need for a more dynamic perspective to spatial equilibrium phenomena. Such a perspective presupposes a more integrated view on locational decisions and emerging market patterns, thus necessitating an economic growth perspective. Consequently, trade and location are endogenously determined in modern economic growth theory, as developed inter alia by Krugman (1991). This also means that factor mobility, transportation costs, and transaction costs become an integral part of modern theories on location and urban or regional growth.

In a recent study by Fujita et al. (1999), the authors offer an attempt to retrack economic geography (and regional science), while they also aim to build a 'new economic geography' based on a few rigorous economic principles. The authors signal a regrettable dividing line between mainstream economics and the economics of location. They aim to build a bridge on the basis of a few simple (certainly not universally valid) concepts, in particular the imperfect competition model marked by increasing returns to scale (originating from Dixit and Stiglitz, 1977). In an open (multiregion or multicountry) system various types of spatial agglomeration patterns may emerge, depending inter alia on transport costs, forward and backward linkages, and immobility of resources. The authors offer a new perspective in their effort to bring general economics closer to regional economics. They illustrate their arguments by referring

to core-periphery phenomena, agriculture, urban systems, city size, transportation, international trade, and industrial clustering. The book forms a clear manifestation of the rigor of solid economic analysis for the explanation of the spatial patterns and evolution of economic activity.

The two pillars of regional economics are certainly formed by agglomeration economies and generalized transportation costs. Much emphasis is made in the book on the economic analysis of urbanization and scale advantages, but less attention is given to transportation costs. In our era of ICT development where many economists advocate the 'death of distance,' it would have been preferable to pay more attention to both psychological and virtual distance costs, and their implications for the spatial organization of our world (see Section Modern Residential Location Behavior in a Network Society: The Death of Distance).

The spatial concentration of economic activity has also prompted an accelerated interest in innovation and entrepreneurship in large urban or industrial agglomerations. The recent literature in geography and regional science has focused much attention on the innovative behavior of entrepreneurs, as well as on the urban seedbed conditions for entrepreneurship and innovativeness (see Kourtit et al., 2011).

It is clear that a further integration of location theory, transportation science, trade theory, innovation theory, and industrial organization seems to be a necessary condition for a rigorous way forward.

Where Do People Wish to Live?

The locational choices of households can be looked at from many perspectives exemplified by a great variety of historical, cultural, social, economic, and geographical views. The most prominent and visible pattern in the spatial distribution of households is the clustering of people in the vicinity of firms that demand workers for their economic activities. For example, the Industrial Revolution, based on new, steam-driven technology, created mass-produced goods at particular geographical locations where the inputs for the industrial production process were found. The workers needed for this new mass production of goods were forced to settle near the factories, given the limited transport facilities at the time and their low financial means.

The ultimate example of spatial clustering of economic agents (firms and households) is observed through city formation and city growth, both in developed (industrialized) countries and in developing countries. Nevertheless, some people do not live in urbanized areas with major employment centers, but commute from their home regions to their workplace in the city. This travel distance of households from home to work forms the principal focal point in the classical urban location theories that were developed to explain the spatial structure of agglomerations (see Alonso, 1964; Muth, 1969; Mills, 1972).

The old economic wisdom on urban location decisions of households builds on the functioning of the market for land from which urban location patterns were derived through the application of standard economic laws of supply and demand. The classical, elementary model for the urban location of households considers the decision-making process of households as a place-utility maximizing process in which the travel distance from home to work (commuting distance) plays a crucial role. For reasons of expositional convenience, company businesses are supposed to be located in the center of the agglomeration (but this was relaxed in later versions of the classical models). In this case, all households would prefer to live in the center, if differences in land prices across the urban space were not yet taken into account (thereby minimizing their commuting costs). However, the excess demand of households for locations in the vicinity of the business center forces the prices for this scarcely available land up, because the households are willing to pay more for central locations. Now, a fundamental locational choice for households emerges in which they have to trade-off the conditions of living near the center (low commuting costs, but high costs for housing) with the countervailing features of living at some further distance of the center (high commuting costs, low housing costs). The difference in the costs for land (housing) will be determined – in the spirit of classical urban models – by an equilibrium state of the land market in which the household's well-being (or utility) is equalized over all possible locations within the urban space. The main economic principle of bidding for those (urban) locations that households consider to be attractive in some sense remains valid, when differences across households (e.g., size, income, preferences), the existence of urban employment subcenters, governmental regulations of land and housing markets, and other locational variations or neighborhood characteristics (public and private facilities, environmental amenities, green areas, socioeconomic composition) are taken into account (see Straszheim, 1986). This means that besides valuing shorter distances to the city (employment) center, households bid up housing prices in higher-valued neighborhoods.

Residential Relocation of Households: Search and Thou Shall Find

People do frequently move to other locations to obtain better housing during the course of their expected lifetime. There are several reasons for this change of residence and most often the motives are job-related (labor migrants) or housing-related (size and facilities of the dwelling unit). The residential move could, of course, also be due to health, family moves, change in household composition (marriage or living together, childbirth), or improved transport facilities. Short-distance moves are usually associated with housing-related reasons (such as a change in household income), whereas long-distance residential moves are likely to be triggered by job changes (see Clark and Van Lierop, 1986). In general, people consider moving when some external shock makes the current location suboptimal, that is, the household becomes dissatisfied with the dwelling itself, the housing environment (social bonds with people living in the neighborhood, availability of parks, recreational facilities, playgrounds, and schools), or the employment opportunities that are accessible from the current location through commuting. This shock may originate from the internal household circumstances (e.g., childbirth or a divorce), be related to market forces (rent, interest rate,

commuting costs) or be due to externalities such as noise caused by new neighbors or, e.g., pollution of the local environment (air, water, soil).

The propensity to move creates a search process in which households try to improve their current situation. At the heart of this search process, households face a lack of information on potential dwellings at alternative locations and are confronted with time and money costs to acquire such information. Moreover, in the search process the household has to decide on the spatial area of search. A residential move will then be made when the expected gain is higher than the moving costs (this may also include nonmonetary costs related to the psychological value attached to the local social network of contacts).

Accordingly, it is well-known that residential moves are affected predominantly by age which represents the stage in the life cycle. Furthermore, transaction (moving) costs often prevent households from moving in response to small changes in the environment. From a methodological point of view, the search behavior of households on the housing market can be investigated appropriately by employing duration modeling techniques in which variations in residential duration are used to analyze housing market dynamics (preferably in a spatial context). Recent theoretical developments along the search-theoretical angle have also stressed the simultaneity of the decision to move and to change jobs, thereby taking into account commuting costs (see Van Ommeren et al., 1996). One of the central recent issues in this respect is also whether people follow jobs (as outlined in the classical urban models) or jobs follow people (as argued in previous sections on industrial location). Empirical research has established evidence that firms tend to follow – but not to lead – workers to suburban areas (see White, 1999).

An important recent megatrend is the rise in foreign migration. We live in the 'migration age.' Modern urban agglomerations attract an unprecedented mass of migrants in search of new opportunities. The consequences of this urban migration influx are sometimes uncertain, but lead to significant changes in housing markets, labor markets, consumption patterns, and social cohesion. A systematic methodology is needed to investigate this multitude of impacts, called Migration Impact Assessment (see Nijkamp et al., 2013).

Finally, it should be emphasized that in many Western societies the possibilities to realize the demand for particular locations are limited by regulatory measures on the housing markets and restrictive spatial planning policies. In many Western countries, both housing demand and supply are regulated extensively (by means of price regulation, allocation devices by local communities, etc.).

Modern Residential Location Behavior in a Network Society: The Death of Distance

Many households now live and work in an information society in which economies are characterized by networks and increasingly build on the input of knowledge (and less on the classical production factors capital, labor and land). This new paradigm for the world economy – in which ICT plays a decisive role (see Castells, 1996) – has significant consequences for the spatial distribution of activities (at the macrolevel) and for the location decisions of agents (at the individual level). The globalizing world creates footloose agents that are not tied to specific geographical places (either market- or input-related), but at the same time localization trends can be noticed with an increasing importance of local locational factors (such as favorable living conditions, the environmental quality of life, and housing facilities).

So what are the main effects of ICT on household location and relocation decision-making? First, ICT greatly influences the search process for new dwellings (and alternative locations), since, search costs are greatly reduced by easy and full access to information (e.g., via the use of Internet). It may, however, be difficult to filter adequately information through these new media and also to obtain reliable information. Moreover, the actual moves still remain to be costly because of monetary and nonmonetary (psychological) moving costs. Second, the ICT-revolution, based on rapidly improving information transport, has initiated a process of internationalization and globalization, and the emergence of the service (network) economy. More specifically, technological progress leads to larger communication flows between firms and households in different regions and cities. In addition, the immaterial character of information removes physical barriers for households in their locational preferences. As a consequence, geographical distance becomes less and less important (because of the Internet, e-mail, and fax); this seems to be the death of distance because of the enormous decrease in communication costs. At first sight, people may choose to work at any place they prefer, thereby enabling them to live where they want without taking into consideration the transportation (commuting) cost, as was highlighted in the classical view on household location behavior. However, it also appears that local networks of firms are vital to the exchange of so-called tacit knowledge (embodied in people) by means of face-to-face contacts. For example, headquarters of major companies often prefer to be located in large agglomerations with multimodal transport facilities (especially by air). This implies, then, that geographical proximity remains an important factor in the (re)location decision of particular groups of households. Consequently, the basic trade-off for households between commuting costs and housing costs does not disappear in their locational choice process.

Location of Public Facilities

As has been argued in the previous sections on household locations, the proximity of private and public facilities will affect the locational decisions of households. From the household's perspective, the location of facilities is taken for granted. The suppliers of facilities do also have to consider the geographical location of their services (given the location of potential customers). In the real world, one observes that a wide range of services to local inhabitants is controlled by public authorities either at the local or at a regional/national level. The various types of public facilities can be classified as follows (see Johansson and Leonardi, 1986).

Travel-to facilities: consumers visit services offered such as schools, libraries, concert buildings, parks, hospitals, etc.
Insurance service facilities: consumers are protected against emergencies due to the existence of certain facilities as fire brigades, dikes, police force, army, etc.
Delivered-from facilities: consumers obtain benefits (or costs) at the place of residence as a result of certain facilities such as broadcasting, pollution from airports, etc.

In case of the first two classes of facilities, consumers travel to the service concerned and the received benefits will be distance-dependent (due to transportation costs). For the third class, the consumer obtains the services at home.

In general, facilities are considered to be public if the services supplied by the public authorities also have a 'public good' character. In short, consumption of a public facility does not hinder the consumption by other consumers of that same good (in technical terms, this means that public goods are nonexcludable, nonrejectable, and allow for joint consumption). Furthermore, the public authorities decide on the particular location of the public facilities. Therefore a major concern in this location decision is given to the distance of consumers to the service at hand. The distance dependence does, however, also imply that the public goods character is not complete in the sense that some will have easier (less expensive) access to the service than others. To sum up, the authorities first have to select their set of public facilities (that is, they have to estimate the demand for public goods) and next, they have to choose how to locate these facilities, given the spatial distribution of potential consumers.

A well-known hypothesis on the allocation of public facilities across space originates from the early work of Tiebout (1956) who postulated that people reveal their preferences for local (municipal) services by 'voting with their feet.' By this 'feet-voting' behavior, Tiebout meant that households migrate to municipalities that offer the best combinations of preferred services and associated taxes. It also gives municipalities the scope to affect the supply of facilities. As a consequence, local communities can influence the size and composition of their inhabitants (through the in- and outmigration of households) as well as their local tax base to finance these facilities. Of course, households will differ in their spatial ('voting by feet') reactions to the provision of various types of facilities. For example, young households with children will probably be attracted by places of residence offering educational services, playgrounds, and recreational amenities, whereas older households are more likely to move to places with support and care services and social-cultural amenities. One of the most important implications of the concept of 'voting by feet' is that the allocation of goods takes place more efficiently than with majority voting. This conclusion does, however, presuppose that housing search and moving are costless, ideal places can be found for each household, and that local goods do not yield benefits to people living outside the community. This set of conditions is hard to meet in practice.

To conclude, the ultimate challenge to analyze jointly household location and public facility location would require an interactive modeling framework of spatial equilibrium in which household locational choices affect governmental decisions on public facility location and vice versa.

Concluding Remarks

Location theory is essentially the heart of economic geography and regional economics, but it is also linked increasingly to industrial organization and trade theory. In particular against the background of the current globalization process, location theory is positioned in a global force field. This force field leads to many rapid responses and behavioral adjustments of business firms, so that stable and robust locations are increasingly replaced by nomadic types of business behavior. The rapidly emerging technological changes (including ICT) encourage location theory to become a battlefield of industrial forces. Clearly, this dynamic evolution has both advantages and disadvantages, and much empirical work would be needed to find out the pros and cons of this dynamic change.

In recent years, we have witnessed the emergence of 'new economic geography' as a conceptual framework for a better understanding of the complex space-economy (see Fujita et al., 1999). In this context, an attempt is made to relate spatial economic behavior of agents to scale and agglomeration economies as well as to open spatial interaction movements (trade, transport, etc.).

It also ought to be noted that from an economic perspective much attention is given to rational behavior of individual firms or households. In reality, we observe many behavioral responses which are instigated by derived factors, such as neighborhood effects, uncertainty analysis, intrafirm transaction strategies, outsourcing mechanisms, etc. This suggests that also the behavioral basis of location theory certainly needs to be reinforced.

Finally, the space-economy is by no means static. It offers a dynamic picture, with large changes in the spatial pattern of human activity. An important modern trend is the spatial movement of people in the current urbanization trend. More than one half of the world population is living in cities, and there is for the time being no reason to expect a declining trend in urbanization. The creativeness climate in modern cities (see Florida, 2001), the knowledge base offered by large agglomerations (see van Geenhuizen and Nijkamp, 2012), and the concentrated variety in choice options in urban areas (see Glaeser et al., 2001) shape a geographical arena where people wish to live. Consequently, locational behavior and urbanization will increasingly have to be seen as two sides of the same coin.

Logic and Linguistics

Thomas Ede Zimmermann, Goethe University Frankfurt, Frankfurt, Germany

Abstract

Logical concepts and techniques are widely used (1) as tools for linguistic analysis and (2) in the study of the structure of grammatical theories. As to (1), the classical field of applying logic to linguistics is the analysis of meaning. The key concepts of linguistic semantics, including the very notion of meaning, are frequently defined in terms of, or in analogy with, concepts originating in formal logic. Moreover, algorithms translating natural language into logical symbolism are used to give precise accounts of, and allow comparison with, the semantic structure of natural language. Concerning (2), a central idea of generative grammar has been to specify logical characteristics of linguistic theory and study their repercussions on the complexity of the object under investigation; i.e., language.

Although the founding fathers of modern logic showed some interest in the analysis of meaning in natural language, solid links between the two disciplines of logic and linguistics had not been established before the middle of the twentieth century. In the late 1950s, logical techniques were first applied to the analysis of grammars as theories of linguistic competence. These applications rapidly developed into the field of mathematical linguistics and subsequently became a central part of theoretical computer science. They will be briefly addressed in the second part of this article. The tightest connections between logic and linguistics, however, grew out of the (re)discovery of logical analysis as a tool of natural language semantics, starting with the advent of Montague Grammar in the early 1970s. The role of logic in the analysis of meaning forms the subject of the first part of this article.

Logic and Natural Language Semantics

The influence of logic on natural language semantics starts with the key notion of the field: meaning. Following the tradition of analytic philosophy (cf. Ammerman, 1965), many linguists take a 'realistic' approach to meaning that makes abundant use of logical apparatus. The basic ideas of the logical analysis of meaning will be explained in The Logical Approach to Meaning section. The Logic and Language section is concerned with some more specific relations between languages of formal logic and natural languages such as English (see Barwise and Etchemendy, 1990; Gamut, 1991 for introductions to modern logic from a semantic perspective).

The Logical Approach to Meaning

A primary goal of semantic theory is to describe the *sense relations* that competent speakers perceive between expressions of a language (cf. Lyons, 1968: Chapter 10; Larson and Segal, 1995: Chapter 1). Thus, for example, knowledge of the following facts about English phrases is part of native speakers' semantic competence: (1) *brown paper bag* is more specific than, or *hyponymous* to, *paper bag*; (2) *blonde eye-doctor* and *fair-haired ophthalmologist* are *synonymous* in that they necessarily apply to the same persons; and (3) *Mary owns a dog* and *Nobody owns a dog* are *incompatible* with each other. Many sense relations can be expressed in terms of *entailments* between sentences: (1) holds because *This is a brown paper bag* entails *This is a paper bag*; (2) holds because *This is a blonde eye-doctor* and *This is a fair-haired ophthalmologist* entail each other; and (3) holds because *Nobody owns a dog* entails *It is not the case that Mary owns a dog*. A theory that correctly predicts the entailment relations holding between the sentences of a particular language may therefore be expected to go a long way toward accurately describing its sense relations in general.

In modern logic, the notion of entailment has been successfully formalized by means of *truth conditions* (cf. Zimmermann, 2011): statement *A* entails statement *B* if, and only if, any way of making *A* true is also a way of making *B* true. Ways of making statements true are called *models*, which is why the enterprise of describing meaning in terms of truth conditions is known as *model-theoretic semantics*. More specifically, a model consists of a set of objects, the model's *Universe*, plus an *Interpretation* assigning to every nonlogical word a suitable denotation. For instance, the Universe of a specific model might be the set of all numbers, past US presidents, plants, or whatever – any set would do, as long as it is not empty. Similarly, the Interpretation could assign any individual to the name *Mary* – the number 20, Jimmy Carter, my little green cactus – as long as that individual is in the model's Universe; and it could assign any set (even the empty set) to the noun *ophthalmologist*, as long as the members of that set are all in the model's Universe, and as long as it is the same set as that which the model assigns to *eye-doctor*. The idea is that any model in which the individual assigned to *Mary* happens to be a member of the set assigned to *ophthalmologist* makes the sentence *Mary is an ophthalmologist* true; and any model in which the set assigned to *ophthalmologist* happens to be empty, is one that makes the sentence *Nobody is an ophthalmologist* true.

In general, then, a model assigns to each expression of the language a denotation, thereby deciding the truth and falsity of each (declarative) sentence. In fact, the denotation of a sentence is identified with its *truth value*: the number 1 if the sentence is true, and the number 0 otherwise. (Other choices of truth values are possible but less convenient.) Using this

numerical convention and writing $[\![X]\!]^M$ for the denotation of an expression X according to a model M, a statement A thus turns out to entail B just in case, for any model M, $[\![A]\!]^M \leq [\![B]\!]^M$: whenever A's truth value $[\![A]\!]^M$ according to any model M is 1, then so is B's truth value $[\![B]\!]^M$ according to the same model M.

Traditionally, the statements made true by models are logical formulas. In linguistic semantics, there are two ways of adapting models to the interpretation of natural language: either natural language expressions are translated into logical notation (*indirect interpretation*) or models directly assign denotations to them (*direct interpretation*). On either approach, complex expressions, i.e., anything longer than one word, are usually interpreted following the *Principle of Compositionality* (Janssen, 1997): the translation or the denotation of a complex expression consisting of more than one word [like a sentence] is obtained by combining the translations or, respectively, the denotations of its immediate parts [like subject and predicate]. As a consequence, the denotations models assign to (the translations of) natural language expressions tend to be rather abstract. If, for instance, the denotation of the noun phrase *my car*, i.e., a concrete object, is to be obtained by combining the denotations of the noun *car*, which is a set of concrete objects, and that of the possessive *my*, the latter would have to be some 'selection mechanism' that picks out the unique object belonging to the speaker when combined with a set of objects. More abstract denotations turn out to be needed in a compositional treatment of determiners (like *every* and *most*), adverbs (like *quickly*) and prepositions (like *between*). This is one of the reasons why the most common systems of logic, propositional calculus and first-order logic, do not suffice as the basis of indirect interpretation.

The Principle of Compositionality has an important consequence, known as the *Substitution Principle*: if the denotation of a complex expression is completely determined by the denotations of its parts, then one may replace any part by something with the same denotation without thereby changing the denotation of the whole. In fact, the two principles turn out to be largely equivalent (Hodges, 2001). A case in point is the sentence (*a*) *Mary is an ophthalmologist*. If Mary happens to be the speaker's neighbor, then the name *Mary* and the noun phrase *my neighbor* have the same denotation. Hence, if (*a*) is true and thus denotes the truth value 1, then, by the Substitution Principle, (*b*) *My neighbor is an ophthalmologist* has the same denotation as (*a*), i.e., it is also true. While the Substitution Principle appears to make the right prediction in this case, this is not always so. Together with the assumption that sentences denote truth values, the Substitution Principle immediately leads to what, in the philosophy of language, is known as *Frege's Problem* (Frege, 1892): replacing any sentence by another one with the same truth value ought to preserve denotation, which it does not always do. For instance, the denotation, i.e., the truth value, of (*b*) *Nobody doubts that Mary is an ophthalmologist* ought to be preserved when (*a*) is replaced by a sentence with the same truth value. If Mary is an ophthalmologist, the truth value of (*a*) is 1 and hence the same as that of (*c*) *Paris is the capital of France*. However, (*b*) might well be false while (*b′*) *Nobody doubts that Paris is the capital of France is* true. Clausal embedding under so-called *attitude verbs* like *doubt*, *know*, or *tell*, thus turns out to be an *intensional construction*; i.e., one that defies the Substitution Principle.

Various solutions to Frege's Problem have been proposed. Practically all of them employ the idea that, at least in certain constructions, the contribution that a sentence makes to the denotations of larger expressions is not its truth value but something else. According to a widely accepted view (originating with Frege), it is its *informational content*: attitude verbs like *doubt* denote a relation between the individual denoted by the subject and the information conveyed by the embedded clause. A common way of modeling informational content is by means of *possible worlds* – whence the term *possible worlds semantics* (see Barwise, 1989; Devlin, 1991 for alternative approaches). The basic idea is akin to that of measuring the expectance value of an event by the proportion between favorable and unfavorable cases. The cases become possible worlds, the event is the information (as expressed by a sentence) being correct and instead of the quantitative relation between the sets of cases expressed by a ratio, it is the qualitative difference that is emphasized; i.e., which worlds are favorable and which ones are not. Following this line of thought, the informational content of a sentence can be represented by a function (in the mathematical sense) mapping worlds to truth values. For example, the informational content of (*a*) above becomes a function assigning to any possible world the truth value 1 if that world is such that, in it, Mary is an ophthalmologist; all other worlds will be assigned the truth value 0. Each possible world is thought of as representing a specific way the world could be, or might have been – down to the last detail. So the informational content of a sentence will typically assign 1 to an infinity of possible worlds differing in all sorts of aspects that are irrelevant to the truth of that sentence; and it will typically assign 0 to innumerably many worlds differing in matters that do not affect the falsity of the sentence.

In order to give a full solution to Frege's Puzzle within possible worlds semantics, the informational content of each sentence must be systematically determined, which is again done compositionally, replacing denotations by *intensions*. The intensions of sentences are their informational contents, but the notion of intension is more general in that it applies to all kinds of expressions (Carnap, 1947; Montague, 1970). The intension of any expression is its denotation (or *extension*) as it varies from world to world; i.e., a function (in the mathematical sense) assigning to each possible world the extension of the expression in that world. As a case in point, one may compare the descriptions (*d*) *the present capital of France* and (*e*) *the largest city in France*: in some worlds, including our actual reality, their extensions coincide, but given a different course of history, as represented by a possible world w, Reims, though smaller than Paris, would be the capital of France. So the intensions of (*d*) and (*e*) cannot be the same, because they disagree on w (and on many other worlds). In general, then, expressions with the same denotations may still differ in their intensions and hence, given compositionality, in the contribution they make to the informational contents of the sentences in which they occur.

The method of extension and intension complements, rather than replaces, the model-theoretic approach to meaning. Instead of directly assigning arbitrary denotations to expressions, the models of possible worlds semantics couple

each expression with an arbitrary intension, which then, being a function, uniquely determines an extension relative to a given world. Moreover, just like models come with their own Universes, in possible worlds semantics each model is also equipped with its own Logical Space of worlds. This construction originates from *modal logic* (see below) and offers an alternative to the model-theoretic reconstruction of entailment: a sentence *A strictly implies* a sentence *B* if *B* is true in all worlds in which *A* is true; i.e., if the intension of *B* yields the truth value 1 for any possible world for which the intension of *A* yields 1.

Logic and Language

The basic tools of logic-based linguistic semantics – models and possible worlds – had originally been developed for artificial languages designed for specific purposes, like the analysis of mathematical proofs. Logical formulas can usually be paraphrased in colloquial language; the relation between formula and paraphrase is taught in introductory logic classes. Conversely, many constructions in natural language (passive, relative clauses, …) have long been known to be systematically expressible in languages of logic (cf. Quine, 1960); *formalization*, i.e., the art of translating ordinary sentences into logical notation, is also something to be picked up in an introduction to logic. As a side effect of the logical approach to natural language semantics, these relations between natural language grammar and logical notation can be explored in a more rigorous way. We will briefly go through some pertinent examples; more detailed case studies can be looked up in any textbook or handbook on formal semantics (Heim and Kratzer, 1998; Zimmermann and Sternefeld, 2013; von Stechow and Wunderlich, 1991; van Benthem and ter Meulen, 1997; Maienborn et al., 2011/2012).

The most obvious connections between logic and language concern the meaning of *logical words*; i.e., those lexical items that translate the basic inventory of logical formalism: the ('Boolean') connectives '¬'; '∧'; '∨'; … translated as *[it is] not [the case that]*; *and*; *or*; … and the *quantifiers* '∀' and '∃' corresponding to *everything* and *something*. The logicians' versions of the former are combinations of truth values. For example, just like a sentence of the form '*A and B*' is true just in case both *A* and *B* are, '∧' combines 1 and 1 into 1 and the other pairs of truth values into 0. Similarly, '¬' (glossed as *not*) turns truth (1) into falsity and vice versa; '∨' (∼*or*) combines 0 and 0 into 0 and everything else into 1, etc. These combinations of truth values can thus be given by means of the *truth tables* in Table 1.

Even though truth tables work fine as first approximations to a semantic analysis of the words *not*, *and*, and *or* as they are used in mathematical jargon, there is more to the meaning of these words. To begin with, *and* and *or* do not always stand between sentences but may be used to connect almost all kinds of expressions: *every book and a pen*; *see and/or hear*; *true or false*; etc. However, in many cases, these nonsentential uses abbreviate coordinated sentences: *John owns every book and a pen* is short for *John owns every book and John owns a pen*, etc. In fact, nonsentential *and* and *or* can frequently be systematically reduced to the relevant truth tables by a *type shift*, a semantic rule that systematically generalizes combinations of truth values to combinations of other denotations (see Partee and Rooth, 1983; Keenan and Faltz, 1985; Hendriks, 1993). However, even this generalization does not cover all nonsentential uses of these words. In particular, there is no obvious reduction of the group reading of *and*, as in *John and Mary are a married couple*, to the truth table of Boolean conjunction; for a less obvious reduction see, however, Winter (2001). Neither does there seem to be a straightforward reduction of alternative *or*, as in questions like *Shall we leave or do you want us to stay?*, to Boolean disjunction. Certain other semantic aspects that the truth table analysis seems to miss may be captured by pragmatic principles governing efficient use, as opposed to literal meaning (Grice, 1989; Levinson, 1983). As a case in point, the difference between *John lit a cigarette and Mary left the room* and *Mary left the room and John lit a cigarette* may be explained by a general principle of discourse organization, according to which the order of sentences should match the order of the events they describe. More involved pragmatic reasonings have been given to account for the exclusive sense of *or*, according to which *John missed the train, or he decided to sleep late* implies that John did not both miss the train and decide to sleep late.

In addition to the Boolean connectives, standard formal languages of logic contain both a *universal* and an *existential quantifier*, usually translated as *everything* and *something* and expressing properties of predicates: being universal, i.e., true of everything, and being nonempty, i.e., applying to something. Natural language statements are only expressible in standard (first order) logic if they can be rephrased by combinations of Boolean connectives and the two quantifiers. A case in point is the sentence (*N*) *Every boy loves a girl* that can be paraphrased by (*L*) *For everything it holds that either it is not a boy, or for something it holds that it is a girl and the former loves the latter* – which translates into predicate logic as (*F*) $(\forall x)\ [\neg\ B(x) \vee (\exists y)\ [G(y) \wedge L(x,y)]]$. As the logician's paraphrase (*L*) indicates, the internal structure of quantified statements in natural language is quite different from of the corresponding logical formulas. In particular, it usually involves *determiners* like *every* and *a* instead of the natural language quantifiers *everything* and *something*. The difference is that a determiner relates *two* sets, whereas a quantifier makes a statement about *one* set. Thus, in (*N*), *every* relates the set of boys with the set of girl lovers, whereas the quantifier *everything* in (*L*) as well as the universal quantifier '∀' in (*F*) attribute universality to the set of individuals that love girls if they are boys; i.e., the set of those that are either not boys or else love a girl.

Another means of expressing quantification in natural language is by way of certain *adverbs*. In particular, in so-called *donkey sentences* like *If a farmer owns a donkey, he never beats it*, the adverb *never* (on one reading) expresses that the set of donkey-owning farmers that beat their donkeys is empty.

Table 1 Truth tables for Boolean connectives

A	B	¬A *[negation; gloss: not* A*]*	A∧B *[conjunction;* A *and* B*]*	A∨B *[disjunction;* A *or* B*]*
1	1	0	1	1
1	0	0	0	1
0	1	1	0	1
0	0	1	0	0

The very form of this *adverbial quantification* is rather remote from the usual logical formalization; it is not even clear whether in this case, as is usually assumed (see above), the indefinites *a farmer* and *a donkey* correspond to existential quantifiers. In natural language semantics special logical systems have been developed to give a more adequate logical account of indefinites in donkey sentences and related constructions (see Dekker, 2012).

Apart from these structural differences in the formulation of quantified statements, there are also differences in expressive power. In particular, not all natural language determiners can be paraphrased by combining Boolean connectives and logical quantifiers. For instance, it can be shown that a statement like *Most boys are asleep* cannot be expressed in first-order logic (Barwise and Cooper, 1981). Adequate formalizations of such sentences, and hence of natural language in general, again call for more powerful and complex languages of logic (*see* Quantifiers for more about quantification in natural language and its relation to logic).

Logicians have devised various extensions of classical propositional and predicate logic as tools of formalizing reasoning involving specific locutions (cf. Haack, 1974; Gabbay and Guenthner, 2001, vol. 2). For instance, in addition to Boolean connectives, languages of (propositional) *modal logic* (Chellas, 1993; Blackburn et al. 2001) contain a *necessity* operator, usually written as '$\Box$'; a formula '$\Box\varphi$' [read: it is necessarily so that φ] is true *in a world w* of a given model if the formula φ itself is true in all worlds that are possible for (or, technically: *accessible* from) *w*. Combining negation and necessity, it is also possible to express a corresponding notion of possibility as '$\neg\Box\neg$.' Models of modal logic thus contain domains of possible worlds organized by an accessibility relation. Depending on the precise structure of the latter, modal logic can be used to formalize various uses of modal verbs as in *Someone must have been here* (*epistemic* must) or *You may now leave the room* (*deontic* may). However, detailed studies of modality have revealed that these formalizations are at best approximations of the meanings of modal verbs in natural language (cf. Kratzer, 1991). A similar relation is that between *temporal logic* (Venema, 2001) and the tenses and other means of reference to time in natural language (*see* Tense, Aspect, Mood, and Evidentiality, Linguistics of).

Various phenomena have led semanticists to explore alternatives to classical logic with its model-theoretic interpretation assigning one of two truth values to each formula or sentence (see Beaver, 1997). A sentence like (*1*) *John knows that there will be a party tonight* seems to imply (*P*) *There will be a party tonight*; on the other hand, so does its negation (*2*) *John does not know that there will be a party tonight*. But if (*1*) and (*2*) both implied (*P*) in the sense of classical model theory, then (*P*) would be true throughout the models in which (*1*) is true – as well as in those models in which (*2*) is true; i.e., the ones in which (*1*) is false. But then (*3*) would have to be a *tautology*, i.e., a statement that is true in all models; for any model would have to make (*1*) true or false. Giving up this last assumption, one enters the realm of (certain) *nonclassical logics*, the simplest among which are *three-valued logics* with an additional truth value *U* (read: *undefined*) which models assign to sentences like (*1*) if their *presupposition (P)* is not true in them (*see* Linguistic Presupposition for more on this).

The Logic of Grammar

As theories of language structure, grammars themselves have been the objects of logical analysis. The earliest such investigations mark the beginning of generative grammar and were directed to shedding a light on the complexity of human language (see Syntactic Complexity section). subsequent approaches focused on the role of grammatical rules in the activity of parsing, which bears some resemblance to the process of deduction in logic; and more recently, grammatical reasoning has been seen as a nonmonotonic process, thus reaching beyond the limits of classical logic (see Further Issues section).

Syntactic Complexity

A syntactic theory of a particular language may be seen as a body of theoretical statements describing the structure of grammatically correct phrases. Formal reconstruction reveals that these theories come in different formats and complexities (cf. Pullum and Scholz, 2001 for more on this). For instance, a *context-free* description of a language only contains grammatical rules of the form: 'If a phrase of category *B* is immediately followed by a phrase of category *C*, the result will be a phrase of category *A*.' The standard notation for a rule of this form is: '$A \rightarrow B + C$.' Thus the following rule of English grammar is context-free: *if a preposition* (like *about*) *is followed by a noun phrase* (like *corrupt politicians*), *they form a prepositional phrase* (*about corrupt politicians*). In standard notation, this rule reads: '$PP \rightarrow Prep + NP$.' On the other hand, the following would-be rule is *not* context-free: *after a ditransitive verb* (like *give*), *two noun phrases* (like *every kid* and *a penny*) *form an object-phrase* (*a kid a penny*). Rather, the rule comes under the more complex scheme: 'If a phrase of category *B* is immediately followed by a phrase of category *C*, the result will be a phrase of category *A*, provided that it follows a phrase of category *D*'; one just has to put $A =$ *object-phrase*, $B = C =$ *noun phrase*, and $D =$ *ditransitive verb*. Rules of this form are called *context-sensitive*. Using standard notation, they are written as: '$A \rightarrow B + C/D-$.'

The distinction between context-free and context-sensitive rules – and similar distinctions between other kinds of grammatical rules – can be used to define an abstract complexity ranking between languages, the *Chomsky Hierarchy* (after Chomsky, 1957, 1959). A language is context-free (or, as the case may be, context-sensitive) if it can in principle be described by a body of context-free (or, respectively, context-sensitive) rules. Languages in the sense of this definition are arbitrary sets of sentences, which themselves are arbitrary strings of words. It turns out that, in this abstract mathematical setting (known as *mathematical linguistics* or *formal language theory*), though all context-free languages are trivially context-sensitive, the converse is not the case: one can construct languages that are context-sensitive without being describable by any body of context-free rules whatsoever. A famous example is the 'language' $a^n b^n c^n$ whose 'sentences' consist of arbitrarily many occurrences of the 'word' *a* followed as many *b*s, which are again followed by the same number of *c*s. (A proof can be found in Kracht, 2003: Section 1.6.)

In applying these abstract concepts, a language like English is identified with the set of its grammatical sentences, thereby abstracting from meaning or grammatical structure (see Kracht, 2011 for a wider perspective). Given this identification, it is natural to ask for the exact location of human languages in the Chomsky Hierarchy. It may seem that an answer to this question requires complete knowledge of the grammatical sentences of any given language – something that current linguistic research has not attained. However, at least some of these complexity issues can be settled on the basis of partial information about the languages under investigation. In particular, it has been shown that, given the intricate structure of its verb complexes, the Swiss German dialect spoken in Zurich cannot be captured by context-free means (Shieber, 1985); a similar result concerning word formation has been obtained for the African language Bambara spoken in Mali (Culy, 1985), thus proving that natural languages in general are not context-free. See also the discussion in Pullum and Rawlins (2007) on the English *X or no X* construction (as in *Rain or no rain, we are going to have our carnival*) as a possible source of noncontext-freeness.

Further Issues

The fact that ordinary syntactic notation looks rather different from logical symbolism should not distract from the close connections between the two. For instance, as indicated above, a context-free rule only abbreviates a lengthy statement about the internal structure of phrases; and this statement can be easily (though somewhat clumsily) expressed in standard logical symbolism (i.e., first-order predicate logic). This fact becomes particularly important when it comes to the task of *parsing* phrases of a given language according to a given grammar. As a case in point, parsing the prepositional phrase *about Mary* on the basis of the above context-free rule boils down to making a connection between the following three pieces of information: (*I*) *about* is a preposition; (*II*) *Mary* is a noun phrase; and (*III*) if x is a preposition and y is a noun phrase, then $x\ y$ (i.e., x followed by y) is a prepositional phrase. (*I*) and (*II*) are basic facts about English words to be recorded in a *lexicon* (which may be thought of as part of a syntactic description); (*III*) is just a paraphrase of the above context-free rule: '$PP \rightarrow Prep + NP$.' (*I*)–(*III*) obviously entail that *about Mary* is a prepositional phrase, and this is precisely the kind of entailment that can be formalized by means of elementary logic. Hence it should not come as a surprise that there are close relations between parsing strategies and procedures for verifying logical entailments. This connection has been studied in computational linguistics and in categorial grammar under the heading *Parsing as Deduction* (see Johnson, 1991).

The role of logical deduction in grammatical theory is more complex than can be indicated in an article of this length. In particular, certain phenomena like the markedness of grammatical features or the interaction of phonological constraints, seem to call for nonclassical logics that violate the *Law of Monotonicity*, according to which a conclusion once drawn remains correct when more premises are added (cf. Besnard et al. 2003; Prince and Smolensky, 2004).

Logic Models

Joy A Frechtling, Westat, Rockville, MD, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The purpose of this article is to discuss the use of logic models as a tool and consider how logic models can best be used to strengthen research and evaluation studies. We define logic models as a range of visual depictions of a project or program's theory of change or theory of action. The article provides examples of logic models, suggests some historical roots, discusses the development of logic models and how they can be used, and offers a list of their strengths and weaknesses.

Background

The purpose of this article is to discuss the use of logic models as a tool and consider how logic models can best be used to strengthen research and evaluation studies in the social and behavioral sciences. We define logic models as a range of visual depictions of a project or program's theory of change or theory of action. Knowlton and Phillips (2013) offer the following descriptions

> Logic models are a graphic way to organize information and display thinking. They are a visual approach to the implicit maps we all carry in our minds about how the world does or *should* work … Logic models describe the planned action and its expected results.

Critical in their definition and the definition assumed in this article is the belief that a logic model is an approach more than a single template. It is a way of thinking about or deconstructing how one believes "you can get there from here." A logic model makes assumptions explicit and can help to identify gaps or differences in perspectives that otherwise might go unrecognized. Although there are some formats that are more frequently used than others, the approach offers flexibility and is modifiable for different purposes and contexts.

The discussion of logic models in the literature has increased dramatically over the last two decades. An examination of citations in Google Scholar indicates that the term was cited 566 times in 2000 and 3060 times in 2012. A search of ERIC, focusing on the education field, showed that the term was used in the text of studies 16 times in 2000 and 56 times in 2010. While these numbers obviously differ considerably in absolute terms, the message is the same. Logic models are far more in the mainstream today than they were 10 years ago. The idea of logic models has, however, a longer history. According to Funnell and Rogers' (2011) discussions of program theory, the underpinnings of logic models were taking place in the 1950s. In their book, *Purposeful Program Theory*, they provide an illuminating review of the history of program theory leading to the development of visual depictions by the United Way and the W.K. Kellogg Foundation in the late 1990s and early 2000s. Contributors in the last half of twentieth century to the development of this theory include many well-recognized researchers and evaluators such as Daniel Stufflebeam, Carol Weiss, Joseph Wholey, Huey-Tsyh Chen, Peter Rossi, and Len Bickman.

While the nonprofit sector (specifically the United Way and the W.K. Kellogg Foundation) can be credited with leading the charge to use logic models, their acceptance today extends beyond the nonprofit world. Increasingly federal agencies such as Substance Abuse and Mental Health Services Administration, Centers for Disease Control, Department of Education, and the National Science Foundation see the inclusion of a logic model to be an important part of a program description and many different technical assistance efforts have been devoted to helping grantees develop and use logic models as part of their program development. A Google search using the key words 'logic models and the federal government' resulted in a listing of over 7 000 000 potential links (count taken on 13 October 2013).

Logic models are very versatile tools. They can be applied to a range of questions or disciplines. While the examples in this article are taken largely from education programs, logic models are used in such differing contexts as community-based research, studies of judicial procedures, research on health and health interventions, studies of adult learners, and evaluations of preschool service. In a sense while logic models are used to clarify and explicate the content of a program, they themselves are content neutral, being applicable to almost any area when activities or strategies are believed to relate to a specific set of intended or desired outcomes. Additionally, while the examples in this article focus on evaluation studies, logic models can be used for a variety of purposes including needs assessment, structuring research syntheses, supporting program management and monitoring, describing organizational change efforts, and designing dissemination and communication. Logic models have even been applied to describing different evaluation frameworks or approaches (Hansen et al., in press).

What Is a Logic Model?

While there are variations in how logic models are presented, at a minimum they include a set of components – inputs, activities, outputs, outcomes, impacts, and context – and connections between the components (Kellogg Foundation, 2004; Frechtling, 2007) **Figure 1** presents a simple, generic logic model.

Figure 1 Generic logic model.

The components are defined as follows:

Inputs are the resources brought to a project, typically funding sources or the experiences and knowledge of the individuals and institutions involved.

Activities are the components of the treatments that a project is providing. They are the actions that will be taken to move toward the project's goals and outcomes.

Outputs are the products of activities. Outputs document the implementation of an activity in simple, itemized ways. They document the size and scope of the activity.

Outcomes are results or changes in behaviors or learning. Outcomes identify the goals and objectives of the project. Outcomes are typically specified in the short and longer term. How to differentiate short- and long-term outcomes is project specific and determined in large part by the complexity of the changes that are sought.

Impacts are broader changes in systems that can be linked to the interventions or activities depicted in the model. Typically such impacts include, but also extend beyond, the specific units that are the focus of study.

Contextual factors are the special characteristics of a grantee setting that need to be considered in understanding how a set of interventions may play out. Context can include both current context and historical context, as previous experiences may color how a proposed change is perceived. Contextual factors help clarify the nature of the setting in which the project is being implemented and can play a role in identifying challenges that need to be addressed. Understanding of context also helps inform where approaches and findings might and might not be generalizable.

Connecting the components and showing relationships between and among them are a series of arrows and lines which show expected interdependences or consequences. The arrows are a critical part of the logic model, showing what is hypothesized to lead to what. The lines are also important and portray connections between potentially isolated pieces.

Figure 2 presents a simple logic model showing the expected sequencing of events for a program that provides professional development for teachers with the goal of improving skills and knowledge.

By looking at the outcome we see that the objective of the project is to build human capacity. In this case, it is to produce an increase in skills or knowledge. The strategy for achieving this outcome is providing professional supports. The

Figure 2 Simple logic model for a professional development program.

output – counts of attendees – is proposed as a way to document that the professional supports have been offered and have attracted participants. There are two inputs or resources named as critical to supporting the work, funds and the partners' prior experience. Finally, the contextual variables that are hypothesized to be important to consider are the size and age of the institution and competing priorities.

It is important to note that an output is different from an outcome. While the latter captures the result or change that is expected from the activity, the former is just one way of documenting that the activity took place. A common error in the development of a theory of change is confusing outputs with outcomes. In this case, it would be suggesting that number of attendees is the 'outcome.' Attending a professional development session and changing in some way because of that attendance are quite different things.

The logic model portrayed in Figure 2, while useful, is quite simple. It clearly shows what might be considered a sequence of key activities, but fails to express in any detail the theory of action that underlies it. Figure 3 presents another kind of logic model, one that is intended to capture not only the sequence of activities but more of the underlying theory that scaffolds it.

What are the key differences in these two depictions? First, Figure 3 is more explicit about how the professional support is developed and who is engaged in it. The purpose is not to merely provide development but to utilize disciplinary faculty in doing so, reflecting a research-based belief that disciplinary knowledge is essential to high-quality professional development. Second, the graphic also makes a distinction between two complementary sets of activities: the development and implementation of the professional development and the purchase of materials. Both are called out as being part of the theory of action – one addressing the need for enhanced human resources, the other for new and better material resources. Third, the logic model in Figure 3 is more specific about the kinds of skills and knowledge that are expected to occur. Teachers are not expected to increase their skills and knowledge generally, but rather with regard to algebraic concepts. Professional development is not expected to have a generic or broad-based impact, but rather change is expected to be specific to a given set of knowledge and skills. Fourth, this

Figure 3 More complex depiction of a theory of action.

increase in algebraic understanding occurs as a result of both the training and follow-up activities. One without the other is not expected to lead to significant changes. Finally, the increase in understanding of algebraic concepts and misconceptions themselves are an antecedent of additional changes – classroom instruction. However, they alone do not lead to this change. Rather both follow-up activities and new instructional materials are needed to bring instructional change about. Figure 3 is considerably more explicit about what is happening and how these activities, alone and in combination, are expected to lead to desired outcomes.

As illustrated in both the simple and more complex examples given above, logic models are typically contained on one page and constructs are portrayed at a relatively high level. Sometimes, however, it is useful to create a family of logic models, which provide a 'drill down' from this one-page view. For example, if the target of study is a program that encompasses several strands of activities that may be carried out independently, it can be useful to use this family approach to clarify both the theory of action underlying the program and its subparts. Suppose a program is intended to apply cutting edge knowledge about how students learn and the contextual factors that influence this learning to instructional opportunities within and outside of the regular academic environment. Such a program could have different strands, including setting – formal or informal educational environments; focus – curriculum, professional development, technology; and targets – students, parents/community, instructional leaders, each with their own theory of change. While the overall outcome of the program is educational improvement, to understand the program and evaluate it, it is useful to look at the different funding strands and their theories of change.

There are many ways to actually create the visual that captures a logic model. Many templates for creating a logic model have been developed and can be easily accessed using a search engine. The University of Wisconsin is just one site that offers this resource (http://www.uwex.edu/ces/pdande/evaluation/evallogicmodelworksheets.html). Software such as Word, Visio, Prezi, PowerPoint, or Excel can all be used to manually develop your model on the computer. There are also several different software packages that have specifically been developed to support logic model development. These include DoView, Innovation Network Logic Model Builder, and ImpactMap.

As stated above, the logic model graphic described above is only one of the ways of visualizing a theory of change. There are a number of other formats that can be used. For example, some like to use a vertical approach, with inputs on the bottom and impacts on top (see Figure 4). Having the impacts and outcomes at the top of the visual helps promote a focus on what the project is trying to accomplish.

Others prefer a nonlinear approach, feeling that the nonlinear approach conveys a more interactive and dynamic image (Figure 5). Of course, capturing the interactions and potential feedback opportunities that might be expected to occur can lead to the development of a visual which, while accurate, loses the ability to communicate in any easy fashion (Figure 6). Logic model developers must always balance the desire to present all critical details with the goal of creating a visual image that clarifies, rather than confuses, communication.

Figure 4 A vertical logic model.

Figure 5 Simple nonlinear logic model.

Logic Models and Methodologies for Research and Evaluation

The logic model visual has applicability within wide range of research and evaluation approaches. Earlier on we noted the philosophical similarity between program theory and logic models. Both are also similar in that they are applicable to many different evaluation contexts and methodologies. They provide a way of clarifying how a series of activities is expected to lead to a set of desired outcomes, but do not prescribe a specific strategy for assessing whether the theory is correct. Logic models are compatible with a range of approaches to studying a problem, as long as goals for a program can be specified. They can be used to scaffold different evaluation approaches, including participatory evaluation, developmental evaluation, randomized treatment control studies, cost–benefit analyses, needs assessment, and evaluability assessment to name just a few approaches. That said, evaluation type might influence how a logic model was developed with, for example,

Figure 6 Nonlinear logic model with feedback loops.

participatory evaluation including a broader range of stakeholders than one that does not take the participatory approach (see discussion in next section).

Logic models are also useful tools to support investigation at all stages of program development from design to implementation to completion and even scale up or sustainability. The Community Toolbox (http://ctb.ku.edu/, retrieved 14.10.13.) suggests using logic models during planning, implementation, staff and stakeholder orientation, evaluation, and advocacy.

When a logic model is used as part of an evaluation study, it can provide the foundation for looking at implementation, as well as outcomes. Typically formative evaluation which examines implementation focuses on the left-hand part of the logic model, specifically activities and outputs, and summative assessment examines the right-hand part of the logic model, outcomes and impacts. In the example provided earlier, we can use the logic model as a guide for identifying what should be assessed when. A formative evaluation of the program depicted in this theory of action would examine the development and implementation of the needs assessment, identification of program participants, the initial professional development and follow-up support provided by disciplinary faculty, and the purchase of new instructional materials. The summative evaluation would focus on the results of these activities, first examining whether there are changes in understanding of algebraic principles, common misconceptions, and effective classroom practices; and then consider the longer term issues of quality and effectiveness of mathematics teachers, and ultimately the strength of the educational institutions in which they work.

Logic models are, however, silent with regard to how something can be assessed. Whether the theory of change is examined quantitatively or qualitatively is not prescribed by the logic model format. While the logic model helps to identify what should be measured, it does not specify the particular data collection tools that should be used. Again turning to our illustrative model, we note that while the model suggests that the assessment of the 'follow-up support' provided by faculty is important, there is nothing in the model per se that prescribes how to examine this feature. Indeed, this feature could be addressed in several ways. In addition to information on the number of participants receiving follow-up support (which documents implementation), an evaluation could include assessment of the perceptions of the participants regarding this follow-up or even the nature of the follow-up discussions, using surveys, interviews, or focus group. It is important to remember that decisions regarding how to structure the theory of change are different and separate from decisions regarding how enactment of the theory is to be measured.

Developing and Using Logic Models

The development of a logic model is a 'social' activity. It is a process that involves multiple actors, fosters new relationships and understandings, can be contentious as well as smooth, and can look different at different times and in different contexts. While a single person or group may lead the development of a logic model or create an initial draft, the development of a logic model benefits from the inputs and interactions of multiple, key stakeholders who play different roles and may have different perceptions. Of course when collaborative activity is undertaken in developing the model for a specific activity, it is important to first develop a joint understanding of what a logic model is and is not. Partners need to understand what is meant by the key components – inputs, activities, outputs, outcomes, impacts, and contexts – as well as the importance of tracing specific linkages within and among components.

While developing a logic model can be done at any point in a project's evolution, it can be maximally useful if logic model development is initiated at the planning stage and then revisited at strategic points during the project's life cycle. What is strategic depends on the nature of the project and when key reporting events take place. Some projects only look at their theory of change at the beginning and end of the project; others review the logic model each time new data come in or when a reporting event is looming. The important point is recognizing that a logic model should be expected to be a 'living' and developmental depiction. Information gathered from outputs may well lead to suggestions for changes in activities; examination of actual short-term outcomes against the original short-term outcomes that were expected to occur can also lead to changes in project design, timeline, or level of anticipated outcomes. Modifications are to be expected and even celebrated as new information is acquired.

Who is involved in the development of a logic model will differ depending on the project and who is considered a key stakeholder. In some cases, it is sufficient to have program leadership and the researcher/evaluator at the table. In other cases, it may be necessary to include participants and other key stakeholders, such as representative from the broader community in the process. If the logic model is to be part of a participatory evaluation, then the evaluation participants should also be represented at the logic modeling phase. Including representation from a broad range of groups can have a significant payoff in long run, if ownership and

engagement is established. Decisions about the value or worth of an activity can be facilitated when groups with varied roles and initial understandings have been given the opportunity to create a shared vision. However, the more diverse the groups engaged in logic model development, the more challenging the process and the greater the demands on time and resources.

There are many different ways that the discussion can be structured. Sometimes it is useful for the researcher/evaluator to draft an initial version of the logic model and use this model to kick off broader discussion. If the participants have a general understanding of what a logic model is, they can be asked to create their own logic models and bring them for sharing and discussion. In other cases, a meeting might start with a clean slate, allowing the development to occur as a group activity. Each strategy has strengths and weaknesses and may work well or badly depending on the particular nature of the individuals involved. If time is limited, the first approach – starting with a logic model generated by the researcher/evaluator – is likely to be the most cost-effective.

Although the traditional logic model has a linear appearance, starting with inputs and ending in impacts, the development of a logic model rarely starts with inputs and moves successively through the various components, ending with impacts. Especially, when the project is in its planning or early implementation stages, it is more productive to start with what a project is trying to achieve – desired outcomes or impacts – and work backward, identifying more proximate outcomes and assessing their linkage to the activities proposed to accomplish them (taking into account the inputs or resources available). It can be helpful to pose a series of questions such as what are you trying to ultimately achieve? Who or what are you targeting to bring about these changes? Do the activities that have been proposed appear likely to lead to these outcomes? If not, what else do you need to do to bring these changes about? How long will it take for these changes to occur? What factors in your specific environment might be expected to influence the course and speed of change? Can you do what you need to do with the resources you have available? If not, what are the alternatives? In essence, the discussion needs to bounce back and forth or toggle among the components to assess the extent to which they hang together and work as an integrated whole.

Part of the development of a logic model is also clarifying what is meant by achieving a goal and the value of different types of evidence for documenting goal attainment. Especially when a goal is stated at a fairly high level of abstraction, stakeholders may hold different perceptions of how 'success' should be defined. If, for example, a project goal is to improve student learning, participants may define learning in vastly different ways, including solving complex problems, generating new and innovative ideas, performing well on tests, or acquiring new habit of mind. Each of these has value, but would in all likelihood require different strategies or activities to be undertaken. Activities that might be judged appropriate for increasing test score performance might be quite different than those for generating new and innovative ideas.

Development of a logic model and clarifying the meaning of terms can help stakeholders develop a shared vision of what the project is trying to accomplish and how desired goals are to be reached. At the same time, the discussions can unearth differences in perceptions and understandings that in the short run, at least, may cause anxiety and tensions among groups to emerge. Sometimes accord has reached among different stakeholders only by deliberately allowing some terms to remain fuzzy – a potentially dangerous, but sometime necessary tactic. Logic model developers need to be aware of this potential for creating disequilibrium and be prepared to take the time to hear out the different voices and work with participants to reach a solution. Even if there is agreement, however, it is possible that the discussion that goes hand in hand with logic model development will unearth gaps in the projects' theory of change that no one has recognized. For example, it is not atypical for the development of a set of activities to take on a life of their own, with the connection to project goals getting lost in the process. There may be both activities that do not seem to have any necessary connections to desired outcomes and outcomes that do not link back reasonably to activities identified once the theory of change is systematically examined. In such cases, it may be useful to rethink why such activities were included and whether or not some project redesign is needed. Several sessions of discussion separated by time for reflection and regrouping may be needed before consensus can be achieved.

Strengths and Weaknesses of Logic Models

As this article documents, the logic model is a versatile and useful tool with broad applicability to project design, implementation, evaluation, documentation, and dissemination. However, before crowning the logic model as a 'magic bullet,' it is important to recognize that developing and using logic models has both benefits and limitations. On the benefits side, logic models

- make explicit the theory underlying a project and why certain actions should be expected to lead to specific outcomes,
- force clarification and definition of terms that might otherwise remain vague and subject to multiple interpretations,
- identify gaps in a project's structure or logic,
- assist stakeholders with different perspectives to develop a shared vision and understanding,
- clarify roles and responsibilities,
- provide a tool for management and monitoring,
- identify questions that should be addressed and critical junctures for which data should be collected, and
- are flexible and can be modified as new information is received.

On the limitations side, logic models

- can take considerable time and resources to develop, especially if multiple stakeholder groups with different viewpoints are part of the discussion,
- may not serve to clarify a theory of change if overly complex and detailed,
- can become irrelevant if developed and not revisited,
- can become an obsession, if revisited too frequently and changes are made reflecting small modifications to the program,

- are only as good as the thinking that goes into them and may be flawed if participants thinking is flawed, and
- can be misinterpreted, if users confuse terms such as outputs and outcomes or fail to take into account contextual factors.

Abstract

This article examines the development of logical and hypothetical reasoning from early childhood through adolescence and young adulthood. These two forms of reasoning enable adolescents to entertain and coordinate deductively valid and ontologically possible propositions. The development of logical and hypothetical reasoning in adolescence involves both the construction of metalogical knowledge about logical necessity and truth and executive regulation of inferences for systematic thinking. A variety of biological, psychological, social, and cultural factors are known to influence developmental changes in such reasoning.

Adolescence is a time during which new and powerful forms of reasoning emerge, resulting in fundamental transformations in how people think about themselves, others, and the world. Central to adolescent progress is the ongoing development of logical and hypothetical reasoning (Amsel, 2011; Barrouillet and Gauffroy, 2013; Markovits, 2013). Logical reasoning, in its core meaning, is the deduction of conclusions that follow necessarily from given premises. Hypothetical reasoning is the process of creating, and making inferences about, possible worlds, such that (what is believed to be) reality can be compared to alternatives.

The significance of logical and hypothetical reasoning is that they allow the mind to go beyond perceptions of immediately available information to formally and systematically entertain deductively valid and ontologically possible propositions. These two inference skills are implicated in a range of uniquely human activities, from the make-believe play of children to the research practices of scientists. Both the pretending child and researching scientist have been characterized as generating hypothetical alternatives to the way the world is known or believed to be and reasoning logically about their implications and consequences.

The focus on adolescence as a period of major progress in logical and hypothetical reasoning needs justification in light of claims that these inference skills are applied spontaneously by toddlers or, quite the contrary, that they are acquired only with graduate training in science. In contrast to both these positions, Jean Piaget (1972) and Inhelder and Piaget (1958) proposed a qualitative transition in early adolescence (beginning about age 11 or 12 years) to a new stage of 'formal operations' involving advanced levels of logical and hypothetical reasoning. In this article, the authors review research generated over half a century that has supported and challenged Piaget's claims and tested alternative theoretical accounts. The review is organized chronologically, first addressing the roots of these reasoning abilities in young children, their increasingly sophisticated use by older children and young adolescents, the potential for increased control and coordination beyond that, and their promotion with formal education. The review also considers biological, psychological, social, and cultural factors associated with developmental changes in reasoning.

Logical and Hypothetical Reasoning in Young Childhood

In their classic book, *The Growth of Logical Thinking from Childhood to Adolescence*, Inhelder and Piaget (1958) describe major advances in adolescents' ability to reason logically and hypothetically and explain these advances as outcomes of constructing the mental structures of the formal operational stage (Moshman, 2009). Formal operations is the fourth and final stage of cognitive development, when thinking transcends earlier constraints that limited understanding and inference to actions on the world (sensorimotor stage), symbolic representations of the world (preoperational stage), or formal relations (categorical, mathematical) applied to actual situations in the world (concrete operational stage). Inhelder and Piaget's conclusions were based on individual interviews of over 1500 children and adolescents, ages 5 through 16 years, as they solved a variety of physics problems. Their performance reveals an increasing depth of appreciation with age of the logical and mathematical features of the problems and their growing skills to solve them by systematically constructing hypothetical possibilities and inferring their logical consequences. This strict coordination of logical and hypothetical reasoning, which Piaget called hypotheticodeductive reasoning, was seen as central to formal operations.

The Piagetian focus on adolescence has been challenged by information processing theorists, for whom cognitive development in general and the acquisition of inference skills in particular can be explained by the regular and continuous improvement of cognitive processes of memory, attention, and executive control, among others. Information processing researchers have examined young children's logical and hypothetical inference skills to identify the nature of their underlying inferential competence and sources of development. For example, there is evidence that young children could successfully solve simple combinatorial reasoning tasks in which they were asked to generate all the six possible combinations of clothing for a teddy bear who had two tops and three pairs of pants (English, 1993). But there was a substantial decrement in children's performance when the cognitive demands of the task increased by adding more combinations to the two-variable problem (3×3) or by adding a third variable ($2 \times 2 \times 2$ or

2 × 2 × 3). Only adolescents demonstrated inferential competence on the more complex combinatory tasks.

Similarly, there is evidence that young children can solve simple logical reasoning tasks in which they deduce a proposition q from a conditional (If p then q) or universally qualified (all p are q) major premise and the minor premise p (Hawkins et al., 1984; Kuhn, 1977). Their performance on these inference tasks is almost flawless when the content of the premises are congruent with that they know or believe (If the wind is blowing, the flag on the pole is waving; The wind is blowing; Is the flag waving?). However, their performance is below chance when the premise content is incongruent (All birds have wheels; Robin is a bird; Does Robin have wheels?) as such content increases the cognitive demands by requiring that children accept and reason from a disbelieved premise (hypotheticodeductive reasoning). Moreover, even using congruent content, children have more difficulty making the equally valid *modus tollens* inference (if p then q and not q → not p) compared to their performance on the *modus ponens* inference (if p then q and p → q), perhaps because of the additional linguistic demand of processing negations (Note: The expressions on the left of the → are premises and the expression on the right is the conclusion, which may or may not be judged to follow logically from the premises) (Roberge, 1971).

Children also performed particularly poorly when required to inhibit inferences due to an invalid argument, as in the cases of standard fallacious arguments that assert the consequent (if p then q and q → p) or deny the antecedent (if p then q and not p → not q). Invalid inferences are often made because of a failure to distinguish a conditional premise (if p then q), where p is a sufficient but not necessary condition for q, from the biconditional premise (if and only if p then q) where p is both necessary and sufficient for q and thus q is also necessary and sufficient for p (Rumain et al., 1983). Children were shown to inhibit invalid inferences when presented with multiple premises (if p then q, if a then q, if b then q), which highlight that a given antecedent condition (p) is not the only one sufficient for consequent (q), countermanding the invited inference that p is also necessary for q (Rumain et al., 1983). Other research demonstrates that children's performance on conditional reasoning tasks with the premise if p then q improves if they are asked to generate examples of other sufficient conditions for q in the form of instances of not p and q (Markovits, 2013).

Other cases abound of researchers seeking to demonstrate young children's inferential competence. In one line of research, young children have demonstrated the ability to make inferences from premises with incongruent content when they are presented in a pretend context (Amsel et al., 2005b; Dias and Harris, 1988). For example, when the premises *all cats bark* and *Rex is a cat* was presented as part of pretend play activity, 6-year-olds affirmed that *Rex barks* at a rate above chance (Dias and Harris, 1988). Framing empirically false premises as 'pretend' invites children to use their imagination and create a fanciful make-believe world from which they suppose the truth of the premise and infer causes and consequences of the pretend states of affair (Harris, 2000). Make-believe worlds are fanciful in the sense that they are not constrained by and should have no influence on understanding the real world (Leslie, 1987). Young children generally respect this by carefully distinguishing between fantasy and reality, limiting cases where the former impacts the latter (Weisberg, 2013).

Despite limitations in their information processing capacities, young children demonstrate logical and hypothetical inference skills, at least in certain contexts. But most developmentalists, following Piaget, believe logical and hypothetical reasoning continue to develop at least through early adolescence (Amsel, 2011; Barrouillet and Gauffroy, 2013; Klaczynski, 2009; Kuhn, 2009; Markovits, 2013; Moshman, 2011, 2013a), although differing with Piaget and with each other about the details of this developmental transition.

Logical and Hypothetical Reasoning in Older Children and Young Adolescents

Although even young children have logical and hypothetical competencies, older children and young adolescents demonstrate increasing insight about and flexibility in use of these inference skills across different contexts. For example, Andrew Shtulman and Susan Carey (2007) examined the development of judgments about ontological possibilities with 4-, 6-, and 8-year-olds, and college students. Participants were asked to judge whether ordinary (eating chocolate ice cream), improbable (eating pickle ice cream), and impossible (eating lightning) events could occur in real life. Only the college students judged ordinary and improbable events as equally possible, distinguishing them from impossible events. The ability to distinguish improbable from impossible events improved over age as children relied less on whether these events were experienced and more on identifying real-world facts that would preclude impossible events from occurring. The growing capability of older children to reflect on and imagine the real-world status of nonexperienced events was found to generalize across different types of impossible and improbable biological, psychological, and social events (Shtulman, 2009).

The ability to reflect on the ontological status of events is implicated in counterfactual reasoning about states of affairs that could have occurred but did not. Counterfactual reasoning requires the formation of serious possible worlds, which – unlike fanciful make-believe ones – are constrained by reality and can be used to compare it to possible alternatives. Although creating mental worlds of any sort requires the work of the imagination (Harris, 2000), possible worlds can be much more challenging to create than are make-believe ones because of the need in the former to reflect on and evaluate event sequences as ontologically plausible (Amsel, 2011).

Counterfactual reasoning can have emotional consequences of regret upon the realization that one could have acted differently in a situation and thereby avoided an undesirable outcome that has occurred. Although there has been some controversy about when regret is first experienced and judged in others (Rafetseder and Perner, 2012), anticipating potential future regret and taking actions to avoid it appears to develop only in adolescence (Amsel et al., 2005a; Guttentag and Ferrell, 2008).

The greater insight into and flexibility in the use of inference skills by young adolescents is further illustrated in logical reasoning. Older but not younger children distinguish deductive from inductive inferences on the basis of the certainty

associated with the former, an insight that appears to develop further in adolescence (Pillow et al., 2010). Furthermore, young adolescents but not children can explicitly distinguish arguments by their logical validity (e.g., spontaneously categorizing argument 1 as logically valid but argument 2 as logically invalid) irrespective of the truth of the conclusions (Moshman and Franks, 1986).

1. If dogs are bigger than elephants, and elephants are bigger than mice, then dogs are bigger than mice.
2. If dogs are bigger than mice, and elephants are bigger than mice, then dogs are bigger than elephants.

The initial emergence of explicit distinctions between deductive and inductive inferences and between valid and invalid arguments in early adolescence has been characterized as part of a broader acquisition of metalogical knowledge (Moshman, 2011). Metalogical knowledge is explicit conceptual or epistemological understanding about the justifiability of inferential processes and the necessary (as distinct from empirical) nature of logical truth. Correct use of inferential skills is no guarantee that the meaning and significance of the inferences are appreciated or that their justification is understood. The dramatic advance of metalogical understanding in early adolescence is likely associated with the increase in other inference skills demonstrated on logical reasoning tasks. For example, young adolescents no longer need the support of a pretend play context in order to mentally disregard their prior beliefs and knowledge and correctly infer conclusions in conditional reasoning with incongruent premises (Amsel et al., 2005b).

The emergence of increasingly explicit knowledge about logic and reasoning can be attributed most directly to active reflection on inferential processes, including abstraction of their logical form and construction of advanced conceptions of necessity and possibility. Such reflection generally occurs in social contexts of argumentation and justification and is likely influenced by a variety of biological and cognitive factors. For example, brain changes in adolescence are associated with increases in working memory and cognitive control (Paus, 2005) and may enable the construction of higher order metalogical knowledge.

In addition to biological and cognitive considerations, there are also changes in the schooling of older children and young adolescents, at least in cultures with compulsory education. Middle or Junior High school students (grades 6–8 or 7–9) have a much more rigorous curriculum than younger students. Notably, for many, postelementary education is their first exposure to algebra and geometry. Mathematical instruction in these topics has been shown to be related to improvements in students' formal concepts of justification, proof, and equivalence (Alibali et al., 2007; Bieda, 2010), which may also have consequences for their thinking about their own reasoning and, more generally, about the logical nature of mathematics as distinct from empirical matters of science.

Finally, culture itself, and the value it places on higher ordered thinking, may play a role in older children's and young adolescents' tendency to think about their reasoning. Cross-cultural researchers argue that the acquisition and use of higher ordered inference skills depends on whether or not a given culture views them as useful (Cole, 2006). For example, traditional villagers in third-world cultures resist attempts to get them to engage in the simplest forms of logical reasoning when the premises are not known to be true (Luria, 1976). Consider the dialogue between Alexander Luria (a Russian psychologist) and a rural Uzbekistan farmer (Luria, 1976: pp. 108–109). Luria presented the following logical argument: In the Far North, where there is snow, all bears are white. Novaya Zemlya is in the Far North and there is always snow there. What color are the bears there? The Uzbekistan adult replied, "There are different sorts of bears." Luria then repeated the syllogism, and the farmer responded: "I don't know. I have never seen any others…Each locality has its own animals: if it's white, they will be white; if it's yellow, they will be yellow." Luria continued: "But what kind of bears are there in Novaya Zemlya?" The farmer replied: "We always speak only of what we see; we don't talk about what we haven't seen."

In summary, early adolescence is marked by advances in metalogical knowledge and in its use to guide logical and hypothetical reasoning. Inferences come to be intentionally deployed in the service of critically evaluating the logical consistency and ontological plausibility of claims made about the real world. Reasoning, which can be defined as epistemologically self-regulated thinking (Moshman, 2013b), becomes increasingly reflective in its orientation toward justifiable conclusions. This is a notable development beyond the child's use of logical and hypothetical inference skills to create and reason within alternative make-believe worlds.

The progression from fantasy to formality in the scope of reasoning is consistent with the Piagetian account of development. It remains unclear, however, whether all individuals in all cultures achieve something like formal operations. The rural Uzbekistan farmer made famous by Luria gives perspective on the importance of the biocultural context on the development of inference skills. Rather than being intrinsically driven to construct metalogical knowledge or to refine their inference skills in light of such knowledge, adolescents and adults may come to do so because of the biocultural context in which they grow up. The complex interactions between the society, schooling, and social context of young adolescents as they themselves go through the hormonal changes associated with puberty affect their acquisition of inferential skills. In a biocultural context that is supportive of the acquisition of metalogical knowledge and the refinement of logical and hypothetical reasoning skills, inferential abilities reach levels not seen in childhood and may continue to develop well beyond early adolescence.

Further Development of Logical and Hypothetical Reasoning in Adolescence

Many individuals demonstrate improvements in logical and hypothetical reasoning beyond early adolescence. Hypothetical thinking improves as adolescents become capable of making more complex inferences about alternative possible worlds on counterfactual reasoning tasks. For example, Ana Rafetseder and her colleagues presented counterfactual reasoning tasks requiring simpler and more complex inferences (exemplified below) to 6-, 10-, and 14-year-olds and adults (Rafetseder et al.,

2013). Researchers acted out stories with dolls and props and carefully checked participants' understanding of the details of each story before asking the counterfactual question, which in the versions below was "What would have happened if Suzi had taken her shoes off? Would the floor be clean or dirty?" Overall correct performance was much lower on the more complex version 2 (the floor would be dirty, 64%) than on the simpler version 1 (the floor would be clean, 98%) story. Version 2 requires mentally inferring a complex counterfactual outcome in which Suzi keeps the floor clean but Max dirties it when he subsequently walks through it. Only the adults performed equally well on both versions; 14-year-olds showed a very high level of correct performance but still performed better on the simpler version 1 than on the more complex version 2 story. The 10- and 6-year-old children performed significantly worse than the 14-year-olds and adults, with approximately 50% not making a single correct response on version 2 stories. The authors concluded that there remain challenges in creating possible worlds that extend into adolescence.

Version 1. One day the floor is nice and clean, but then something happens. Suzi comes home and does not take her shoes off and makes the floor all dirty.

Version 2. One day the floor is nice and clean, but then something happens. Suzi and Max come home and they do not take their shoes off. Suzi walks in (followed immediately by Max as depicted by dolls) and makes the floor all dirty.

Logical thinking also improves as adolescents become better able to make deductive inferences on abstract conditional reasoning tasks. These tasks provide no knowledge-based counterexamples to support a sufficiency relation between antecedent and consequent. For example, Henri Markovits and Hugues Lortie-Forgues (2011) had participants aged 12 and 15 years make inferences about abstract conditionals (e.g., if a person daigues then they will become a gadoro), which were presented as conditions on the planet Kronus, where there were different names for things than on Earth. The older group outperformed the younger, on average, particularly when resisting making invalid inferences on denying the antecedent and asserting the consequent items. Such errors would be expected if participants assume a necessary and sufficient relation between the abstract antecedent and consequent. These and other results suggest that abstract understanding of conditional premises as sufficient relations between antecedents and consequents may continue to improve at least through age 15 years (Markovits, 2013).

These changes in reasoning documented above occur as part of a broader set of cognitive changes affecting adolescents (Kuhn, 2009). For example, problem solving can be performed more quickly and efficiently by adolescents than by children because a larger range of relevant experiences, knowledge, and heuristics (simplified inference strategies or 'rules of thumb' that lead to quick but sometimes incorrect conclusions) can be automatically activated in memory (Reyna and Farley, 2006). However, the unique challenge of ontologically complex and logically abstract inferences is to inhibit automatically activated knowledge, experiences, and heuristics in favor of making carefully controlled inferences that are intentionally guided by metalogical knowledge. That is, although metalogical knowledge aids in adolescents' understanding what inference to make, adolescents need to exercise executive control over their information processing system in order to make such inferences free from bias resulting from automatically activated experiences, knowledge and heuristics.

It is notable then that middle adolescence is for many a period of improvements in executive function, which is a "deliberate top-down neurocognitive process involved in the conscious, goal-directed control of thought, action, and emotion" (Zelazo and Carlson, 2012: p. 354). The improvement of executive function is linked to neurological changes in the speed and efficacy of neurons in a specific area of the brain's prefrontal cortex and their connections to other brain areas (Blakemore, 2012). Changes in executive function are thought to better enable middle adolescents to inhibit automatic processes and to rely instead on more controlled and deliberate processes in order to make intentional inferences that are guided by metalogical knowledge. Direct and indirect measures of prefrontal cortex functioning have been shown to be related to correctly resolving conflicts between activated beliefs about the truth versus the logical validity of conclusions on logical reasoning tasks (Steegen and De Neys, 2012; Stollstorff et al., 2012).

In addition to executive function and other information processing abilities necessary for improved inferential skills, many adolescents continue to construct metalogical knowledge and increasingly use it to guide their inferences. More broadly, adolescents' reasoning reflects their developing epistemologies, which address the nature of and foundations for their own and others' knowledge claims about the world, especially with respect to normative issues of truth and justification. Many adolescents become increasingly focused on whether knowledge claims are best treated as objective statements that are either factually true or validly deduced, subjective tastes that are merely more or less preferred, or reasonable interpretations that can be rationally evaluated as convincingly justified (Chandler et al., 1990; Kuhn, 1991, 2009; Kuhn et al., 1988; Moshman, 2011, 2013b).

Besides changes at the personal level, there are also changes at the interpersonal level that contribute to adolescent reasoning, including disputes and disagreements with peers and parents. Effective argumentation requires coordinating hypothetical and logical reasoning by highlighting the quality (strengths and weaknesses) of logically possible justifications of knowledge claims (Clark and Sampson, 2008; Kuhn, 1991). Furthermore, argumentation implicates both (1) the availability of metalogical knowledge about the quality of arguments and (2) inferential skills to strategically apply that knowledge in ongoing arguments to defend one's own and undermine one's opponent's positions. Argumentation skills have been shown to improve from childhood to middle adolescence in both ways. For example, 11th grade adolescents, who on average had more sophisticated epistemological understanding than their 7th and 9th grade counterparts, were also generally better able to detect informal reasoning fallacies than younger students (Weinstock et al., 2006). Similarly, adolescents improve in understanding the need to strategically undermine their opponents' positions and not just to defend their own positions (Kuhn and Udell, 2007), although they

may not always implement such a strategy (Stanovich et al., 2012). Finally, argumentation has been shown to improve with practice, particularly with interventions that help arguers reflectively assess the quality of their performance (Chinn and Anderson, 1998; Iordanou, 2010; Udell, 2007). However, cultural variation exits in the perceived value of argumentation as a mean of promoting cognitive development or educational outcomes (Kuhn et al., 2011).

At the societal level, high school education may contribute to improving metalogical understanding of and skills for inferential reasoning. The increased premium placed on STEM (Science, Technology, Engineering, and Mathematics) preparation has resulted in instruction promoting students' abilities to engage in scientific practices (NRC, 2012). Like argumentation, the forms of reasoning practiced by scientists necessitate the coordination of logical and hypothetical reasoning by focusing on generating hypotheses, designing experiments, and evaluating evidence (Inhelder and Piaget, 1958; Kuhn et al., 1988). Proficiency in scientific reasoning involves both the metalogical understanding of formal theory–evidence relationships and skills to apply such understanding to the tasks of formulating and testing hypotheses and evaluating evidence.

Although children have been shown to have a variety of scientific reasoning skills (Morris et al., 2013), evidence points to further improvements beyond childhood and often well into adolescence. Among these improvements are increases in metalogical and epistemological understanding of scientific reasoning and in associated inferential skills. Metalogical developments include more carefully delineated distinctions between theory and evidence, particularly in the forms of evidence that would uniquely test theoretically based hypotheses (Bullock et al., 2009; Kuhn et al., 1988). Epistemological developments include insights into the nature of scientific knowledge, such as recognizing the tentativeness of empirical (as distinct from logical) claims (Sandoval, 2005). There are also corresponding improvements from childhood to adolescence in skills to minimize inferential biases in scientific reasoning. These 'debiasing' skills include reducing the effect of prior beliefs in the evaluation of evidence, generating and evaluating a broader set of possible hypotheses, generating disconfirming and unconfounded tests of hypotheses, and keeping accurate and systematic records (Amsel and Brock, 1996; Klahr et al., 1993; Kuhn et al., 1995; Schauble, 1990, 1996). Although scientific reasoning has been shown to improve with practice and instruction (Kuhn et al., 1995; Schauble, 1996), metalogical understanding of and skills for making unbiased inferences remain less than optimal.

In summary, both logical and hypothetical reasoning tend to become more sophisticated over the course of adolescence, not only when inferences are made individually but also when the two are coordinated, as in argumentation and scientific reasoning. This reflects a developmental trend toward consolidation in the sense that reasoning is better guided by increased metalogical understanding of the logical validity and ontological consistency of inferences and more effectively controlled by an increasingly powerful information processing system. The more powerful information processing system enables the activation and use of justified inference strategies and the corresponding inhibition of automatically activated but potentially biasing experiences, knowledge, and heuristics. But the powerful cognitive tendency to respond automatically remains, resulting in biased reasoning, even when one has metalogical knowledge of valid alternatives. Dual process theoretical accounts of reasoning explain how inferences may be biased by automatically activated information and also identify conditions under which one more readily deploys metalogical knowledge to foster valid reasoning (Amsel et al., 2008; Barrouillet and Gauffroy, 2013; Klaczynski, 2009; Stanovich et al., 2012).

These developments in reasoning beyond early adolescence are neither universal nor inevitable. They are a product of complex interactions among many factors, including cognitive reflection and self-regulation, preferences for deliberative reasoning, neurological functioning, interpersonal interactions, schooling, and cultural context.

Educational and Professional Contributions to Logical and Hypothetical Reasoning

As noted previously, the trajectory of logical and hypothetical reasoning is affected by educational experiences. This effect becomes more pronounced over age. For example, college-educated adults are better able than non-college-educated adults to ignore their prior beliefs about a causal relation and validly evaluate data that contradict those beliefs (Amsel and Brock, 1996; Kuhn et al., 1988). A similar effect of education has been found for argumentation, with a college education related to improved performance on a variety of measures of argumentative skills (Kuhn, 1991), including a reduction of the so-called myside bias, a preference for supporting one's own position over opposing one's opponent (Toplak and Stanovich, 2003).

An intriguing suggestion of the effect of education on reasoning was provided by Demetriou and Bakracevic (2009), who presented conditional reasoning tasks to adolescents (13–15 years of age) and groups of young (23–25 years of age), middle (33–35 years of age), and mature (43–45 years of age) adults who had or had not completed college. The college educated adult groups made more correct responses than the non-college-educated adult groups, with adolescents scoring lower than the educated adults and higher than the noneducated adults. College-educated adults also were more certain of their answers than non-college-educated adults or adolescents, perhaps reflecting their greater understanding of the logical necessity of the inferences they were making.

The authors concluded that education had a beneficial effect on inference skills and understanding. Their data, however, do not rule out the alternative interpretation that students with greater reasoning abilities are simply more likely to successfully complete college. Darrin Lehman and Richard Nisbett (1990) provided stronger evidence for the causal effect of schooling on reasoning as part of a research program exploring the trainability of reasoning. College freshman in the Natural Sciences, Humanities, Social Science, and Psychology were given tests of probabilistic reasoning (requiring hypotheticodeductive inferences) and conditional reasoning (requiring deductive inferences). Although no different in their reasoning skills as freshmen, these students were retested as seniors to assess the changes in their reasoning over time. Students in the natural

sciences and humanities improved substantially in conditional reasoning compared to those in social science and psychology. At least for the natural science students, this improvement was related to the number of math and computer science courses taken, which require understanding abstract formal relations. Students in the social sciences and psychology improved substantially in probabilistic reasoning compared to those in the natural sciences and humanities, which was related to the number of statistics courses taken.

The impact of schooling also applies to professional training in science and the law leading to expertise in forms of logical and hypothetical reasoning. Expertise in science involves acquiring both general hypotheticodeductive inference abilities (e.g., designing simple and direct tests of hypotheses and drawing valid conclusions about theories in light of the evidence) and specific knowledge about the phenomenon of interest (e.g., knowing which variables may be possible causes and how best to test them). One study compared practicing scientists (experts) and college students (novices in how they designed tests in a computer simulation of the causes of the memory spacing effect – that better memory results when studying is spaced over time than massed together (Schunn and Anderson, 1999). Half the experts were psychology researchers in cognitive psychology and so were domain experts and the other half were psychology researchers in other domains and so were task experts. Half the novices had high mathematics SAT scores (high ability novices) and half had average scores (average ability novices). The results demonstrated that there were specific knowledge differences between the domain experts and all other groups. However, the two expert groups made valid hypotheticodeductive inferences more often than the two novice groups. The results suggest that scientists are experts in general hypotheticodeductive reasoning and can apply it outside their immediate domain of expertise.

Another study of professional training in law and psychology demonstrated a similar generality in inferential expertise. Amsel et al. (1991) compared novices and experts in law and psychology in how they evaluate everyday causal statements (e.g., 'kicking the television (TV) set fixed the picture'). As experts in science, psychologists and psychology graduate students tended to make causal inferences more often than experts in law by appealing to statistical evidence of the association between the cause and the effect (e.g., every time the TV is kicked the picture is fixed). As experts in law, lawyers and law students tended to make causal statements more often than experts in science by appealing to counterfactual states of affair (e.g., if the TV had not been kicked it would not have been fixed). The novice groups (police officers and psychology undergraduates) tended not to find the statistical or counterfactual justifications particularly convincing and preferred to make causal statements by appealing to physical mechanisms (e.g., by kicking the TV, the connection between the wires got better).

Conclusion

Children's logical and hypothetical reasoning become increasingly epistemologically self-regulated due to the development of metalogical knowledge and information processing skills, a process that often continues well into adolescence and sometimes beyond. This developmental trajectory is the product of a broad set of factors ranging from biology to culture and includes a central role played by the individual's own motivated search to understand the epistemological basis for valid inference. Logical and hypothetical inferences increasingly come under metacognitive control, and this process may continue for older adolescents and adults who select experiences like attending university and professional school where they acquire expertise in the use of advanced reasoning skills. Logical and hypothetical reasoning is a life span phenomenon: It is present in young children in a variety of forms and continues to be refined well into adulthood in other forms. However, adolescence is a time of especially great developmental importance and potential in the development of such reasoning.

Logical Positivism and Logical Empiricism

Herbert Keuth, Eberhard Karls Universität, Tübingen, Germany

Abstract

Logical positivism and logical empiricism developed in the early twentieth century. The Vienna Circle, the Berlin Society for Empirical Philosophy, and the Lvov-Warsaw School of Logic made important contributions to logic, mathematics, philosophy of science, and language analysis. The Vienna Circle proposed a scientific world-conception. Its goal is unified science; its method is logical analysis, which will unmask traditional philosophical problems as pseudoproblems or transform them into empirical problems. Factual knowledge results only from experience (empiricist), which rests on what is immediately given (positivist). In the 1930s, phenomenalist neopositivism was replaced by realist neoempiricism.

The terms 'logical positivism' and 'logical empiricism' – alternatively 'neopositivism' and 'neoempiricism' – are mainly used synonymously. They refer to a modern version of empiricism, the doctrine that all knowledge about matters of fact stems from and relies on sensory experience and remains hypothetical. Like classical empiricism neoempiricism is 'positive' in a broad sense: it postulates scientific enquiry and rejects metaphysics. In the late nineteenth and the early twentieth centuries, most of modern empiricism was 'positive' also in a narrower sense: all factual knowledge was considered a construction from what is positively given, i.e., from immediate impressions or elements. In the 1930s, this phenomenalist neopositivism has been replaced by a physicalist neoempiricism. Both are called 'logical' because they apply logic for analyzing scientific concepts and clarifying philosophical problems.

Historical Background

Central issues of neoempiricism have their roots in classical empiricism. Empiricism rules out synthetic statements a priori, i.e., necessarily true factual statements. David Hume (1711–76) divided the objects of human enquiry into relations of ideas and matters of fact. Geometry, algebra, and arithmetic deal with relations of ideas. Their statements are intuitively or demonstratively certain, hence a priori. They do not depend on or tell about what exists anywhere in the universe. On the other hand, the contrary of every matter of fact is still possible, because it can never imply a contradiction. As the testimony of our senses is not absolutely reliable, statements about matters of fact are fallible (*An Enquiry Concerning Human Understanding*, Section IV). Hume also proposed a meaning criterion. When we suspect that a philosophical term is employed without any meaning or idea, we need only enquire, from what impression that supposed idea is derived, and if we cannot find any such impression, we will conclude that this term is meaningless (Section II). Hume's discussion of causality showed how to avoid metaphysical hypostatizations of concepts. Causes and effects can be discovered by experience, not by reason. However, no examination of a single object can show that it is a cause or an effect. Therefore, Hume proposed a regularity theory of causation, defining a cause to be "an object, followed by another, and where all the objects similar to the first are followed by objects similar to the second" (Section VII).

Auguste Comte (1798–1857) proposed the terms 'positivism' and 'sociology.' In *Cours de Philosophie Positive*, he maintained that human intellectual development had moved from a theological stage through a metaphysical stage to the positive stage, which relies on scientific method and discovers laws on the basis of relations between phenomena. This holds for natural and social sciences. John Stuart Mill (1806–73) proposed in *A System of Logic, Ratiocinative and Inductive* an empiricist methodology regarding logic and mathematics as the most general empirical sciences, an idea found later in Quine's pragmatism.

Hermann Helmholtz sketched in *Treatise on Physiological Optics* (Helmholtz [1867]1925, [§26, §33]) a realist empiricist epistemology. According to his inference theory of perception we explain our sensations by assuming that they are common effects of external objects and of our nature, but we do not immediately perceive the objects, or our nature, or the circumstance that the objects have an effect on our nature. This realist theory involves the metaphysical assumption of an external world acting on us, which Mach's phenomenalism tries to avoid. All properties that we assign to objects of the external world "may be said to be simply *effects* exerted by them either on our senses or on other natural objects" (1925, 20). As "we see invariably the peculiar sort of interaction occurring, we attribute to the objects a permanent capacity for such effects …. This permanent capacity is … called … *property*" (21). Accordingly, properties are dispositions to lawlike behavior. As we do not perceive the dispositions but only what we take to be their effects, statements that ascribe properties to objects transcend experience. Hence they are fallible.

The physicist and philosopher Ernst Mach (1838–1916) and the philosopher Richard Avenarius (1843–96) proposed a phenomenalist positivism. Avenarius called it empiriocriticism. Lenin criticized it in *Materialism and Empirio-criticism*. Mach rejected Kant's transcendental idealism, in particular the ideas of things-in-themselves and of synthetic a priori knowledge. He considered the atom, which had never been observed, merely a tool for representing phenomena, and he criticized Newton's idea of absolute space and time. Mach's philosophy of science tries to avoid all metaphysical concepts and assumptions. Factual knowledge is considered a conceptual organization of the data of

sensory experience. Hence statements on facts must be empirically verifiable. Mach's phenomenalist construction of the world in *The Analysis of Sensations* ([1886]1897) starts from his contemplation of the spatial boundary of his body. His senses provide findings from outside and inside this boundary. The latter are psychical; the former are physical and can be dissolved into elements like colors and tones. Elements that depend on findings both from outside and from inside are sensations. The complex of what is psychical to Mach is his ego. As the elements of his neighbors are not given to Mach and vice versa, there is no intersubjectively common boundary between the physical and the psychical, rather there are common elements of both districts. Taken by themselves the elements are neither physical nor psychical. This neutral monism avoids the body–mind problem. Obviously Mach is not an ontological but a 'theoretical' solipsist. The objects of the real world are complexes of sensations; hence, there is no need to postulate metaphysical things-in-themselves. Science describes functional interrelationships between complexes of sensations. By learning science we profit from the experience that others have made. Science is a process of adaptation. The most exact and most economical descriptions are most helpful in everyday life.

Gottlob Frege (1848–1925) laid in *Conceptual Notation* ([1879]1972) the foundations of mathematical logic. He introduced variables and functions into logic in an attempt to show that arithmetic is a branch of logic. Concepts are a special class of functions. His program of logicism is worked out in *Basic Laws of Arithmetic* ([1893]1964) where he tries to derive the laws of arithmetic from logical axioms. In 1902, Russell informed Frege that his system implies the antinomy of the set of all sets that do not contain themselves. Frege's work is the first complete example of the logical analytic method in philosophy.

In *The Principles of Mathematics* (1903), Bertrand Russell (1872–1970) stated the philosophical case for logicism. To avoid the antinomy, he proposed the theory of types. In *Principia Mathematica* (1910–13), Russell and Whitehead tried to demonstrate that mathematics is a branch of logic. However, Gödel's first incompleteness theorem (1931) shows that this demonstration is impossible. In *Our Knowledge of the External World* (1914), Russell writes, "the study of logic becomes the central study in philosophy: it gives the method of research in philosophy, just as mathematics gives the method in physics … all this supposed knowledge in the traditional systems must be swept away, and a new beginning must be made" (Section 6). Carnap felt as if this appeal had been directed to him personally.

After reading Frege and Russell, Ludwig Wittgenstein (1889–1951) turned from engineering to logic and mathematics. In *Tractatus Logico-philosophicus* ([1921]1922), he proposed a picture theory of language, according to which a proposition can picture a fact because fact and proposition share a common structure. For each atomic fact there is a corresponding atomic proposition. More complex molecular propositions are constructed from atomic propositions by means of logical connectives. What cannot be pictured cannot be said. The sentences of logic and mathematics do not make statements on the world or on numbers. They do not have linguistic meaning (6.21). They all say the same, i.e., nothing (5.43). According to Wittgenstein philosophy is not a set of theories but an activity. Its task is to clear up confusions arising from misunderstandings of language (4.112). His logical atomism strongly influenced the Vienna Circle. Wittgenstein later rejected logical atomism and argued that the meaning of words depends on their role in language games.

Neoempiricist Circles

From 1907 to 1912, a group that is sometimes called the First Vienna Circle met informally to discuss epistemological and methodological problems of modern physics. It had gathered around the physicist Philipp Frank (1884–1966), the mathematician Hans Hahn (1879–1934), and the economist and sociologist Otto Neurath (1882–1945). The mathematician Richard von Mises (1883–1953) was a corresponding member. They tried to retain the most essential points of Mach's philosophy of science and supplement it by Henri Poincaré's conventionalism and Pierre Duhem's holism. Other fields of their interest were the foundations of mathematics and logistic. Poincaré (1854–1912) had argued that, as we cannot tell whether physical space is Euclidian or non-Euclidian, our choice between geometries is a matter of convention. There is no true scientific hypothesis, rather we choose the hypothesis that is most advantageous (*Science and Hypothesis* [1902]1905). Duhem (1861–1916) had argued that it is impossible to test any physical theory separately. Rather in each case the whole of physics is tested (*The Aim and Structure of Physical Theory* [1906] 1954). In 1912, Frank left Vienna to succeed Einstein in Prague.

The Vienna Circle

In 1922, the physicist and philosopher Moritz Schlick (1882–1936) obtained the chair for the philosophy of the inductive sciences at the University of Vienna previously held by Mach and Boltzmann. A discussion group gathered around his seminar and met regularly since 1923. It was called the 'Schlick Circle' from within and soon the 'Vienna Circle' from outside. Prominent members were Hans Hahn; Otto Neurath; the philosophers Herbert Feigl (1902–88) (who in 1931 proposed the label 'logical positivism'), Friedrich Waismann (1896–1959), Victor Kraft (1880–1975), Felix Kaufmann (1895–1949), and Béla Juhos (1901–71); and the mathematicians Karl Menger (1902–85) and Kurt Gödel (1906–78). Philipp Frank cooperated while in Prague. In 1926, Rudolf Carnap (1891–1970), who had studied mathematics with Frege, joined the circle.

Among the subjects discussed were Einstein's theories of relativity; Wittgenstein's *Tractatus*, which suggests a verifiability criterion of meaning (4.063) and the idea that the sentences of logic and mathematics do not express thoughts; Mach's phenomenalism, which inspired Carnap's *Aufbau*; the character of observation or protocol sentences; and the construction of a metalanguage for the syntactic analysis of scientific languages.

In 1928, the Ernst Mach Society (Verein Ernst Mach) was founded. The choice of its name shows its basic orientation: science free of metaphysics. Originally initiated by the Austrian Freethinker Alliance (Freidenkerbund Österreichs) it became

the platform from which the Vienna Circle addressed a wider public in order to disseminate the findings of the exact sciences and to further modern empiricism and a new organization of economic and social relations. Several members, in particular Neurath, Carnap, and Edgar Zilsel (1891–1944), supported anticlerical and socialist positions. In 1929, the Ernst Mach Society published the booklet *The Scientific Conception of the World: The Vienna Circle* ([1929]1973), which contains a summary of positions common to the members of the Vienna Circle and was dedicated to Schlick. It is the first volume of a series of publications of the Ernst Mach Society. In 1931, Carnap went to Prague, where he and Frank formed a branch of the Vienna Circle, and Feigl emigrated to the United States. In 1934, the Ernst Mach Society was dissolved by the Dollfuss government, Neurath emigrated, and Hahn died. In 1936, Schlick was assassinated and Carnap left Prague for Chicago. The circle continued in a small private discussion group led by Waismann until he emigrated to England in 1938.

The Berlin Society for Empirical Philosophy

In 1928, the physicist Hans Reichenbach (1891–1953), the mathematician Kurt Grelling (1886–1942), and the logician Walter Dubislav (1895–1937) founded in Berlin the Society for Empirical Philosophy (Gesellschaft für empirische Philosophie). Other members were the philosophers Carl Gustav Hempel (1905–97) and Joseph Petzoldt (1862–1929) and the mathematicians David Hilbert (1862–1943) and Richard von Mises. In 1930, Carnap and Reichenbach took over the journal *Annalen der Philosophie* and renamed it *Erkenntnis*. Its new program was to pursue philosophy not as an isolated discipline but in closest connection with the sciences. Reichenbach called this project 'logical empiricism.' On the proposal of Hilbert the Berlin Society was in 1931 renamed 'Society for Scientific Philosophy.'

Together the Vienna Circle and the Berlin Circle organized congresses on epistemology and philosophy of science, some of them preparatory: in Prague 1929; in Königsberg 1930, where Gödel announced his proofs of the completeness of first order logic (his doctoral dissertation of 1929) and of the incompleteness of arithmetic (published in 1931); in Prague 1934; then the international congress for scientific philosophy in Paris 1935; and the international congresses for the unity of science in Copenhagen 1936, in Paris 1937, in Cambridge, UK, 1938, and in Cambridge, USA, in 1939.

The Lvov-Warsaw School

Kazimierz Twardowski (1866–1938) established the Lvov-Warsaw School of logic, which studied the foundations of mathematical logic and analyzed the relationship of language and knowledge. Among its members were his doctoral students Jan Łukasiewicz (1878–1956) who developed the Polonian notation and formalized a system of three valued logic, Stanisław Leśniewski (1886–1939), Tadeusz Kotarbiński (1886–1981), and Kazimierz Ajdukiewicz (1890–1963) who in 1920 developed a deductive theory for the study of logic based on syntax. Alfred Tarski (1901–83), doctoral student of Leśniewski, established scientific semantics. In 1933, he defined the concept of truth in formalized languages. To avoid antinomies like that of the liar he separated object- and metalanguage. In Vienna, Tarski met Gödel and worked with Menger. Tarski's metalogic influenced Carnap. Ajdukiewicz and Kotarbiński also cooperated with the Vienna Circle.

The Scientific Conception of the World

The scientific conception of the world is not a collection of theses; rather it consists of a basic attitude, common points of view, and a direction of research. The task of philosophical work is the clarification of problems, concepts, and assertions, not the production of specifically philosophical theses or even dogmas. The scientific world-conception can best be characterized by two main features. First, it is empiricist and (in 1929) positivist; it expects factual knowledge only from experience (empiricist), which rests on what is immediately given (positivist). Therefore, it rejects all metaphysical philosophy. Second, its method is logical analysis of concepts and statements both of natural and formal languages. This method essentially distinguishes modern empiricism from classical empiricism. Applied to traditional philosophical problems it will either unmask them as pseudoproblems or transform them into empirical problems.

Unified Science

The goal of the scientific world-conception is unified science. In 1938, a series of publications started, the *International Encyclopedia of Unified Science*, which was never completed. Nineteen monographs appeared from 1938 to 1969 and were finally collected in two volumes. Unified science may be characterized by two requirements. The weaker one is all sciences apply empirical methods and use the physicalist language or thing language (which is not identical with the language of physics). The stronger requirement is the laws of all sciences are derivable from physical laws. This program is called reductionism. Since 1930, parts of medicine have been reduced to biology, parts of biology to chemistry, and parts of chemistry to physics. As long as sciences produce new theories, the reduction of all sciences to physics will never be complete, and neoempiricists cannot want that science should ever come to a standstill just to complete unified science. Therefore, they will have to be content with sporadic partial reductions. However, most criticism of the idea of unified science is directed against the weaker requirement, because it rules out scientific statements on specifically mental entities (as e.g., minds that are independent of brains) and specific nonempirical methods postulated in the humanities (as e.g., Verstehen [understanding], introspection, or intuition).

The Kernel of Neopositivism

Carnap's *Der logische Aufbau der Welt* ([1928]2003, *The Logical Structure of the World*) is a crystallization of logical positivism, its most influential book. It is empiricist, phenomenalist (positivist), and antimetaphysical. Frege and Russell had attempted to reduce all logical and mathematical concepts to a few fundamental concepts. In the *Aufbau* Carnap tries to sketch how the same can be done for empirical concepts.

A system of concepts could be built on a physicalist basis, but he chooses a phenomenalist basis, because it represents not only logical but also epistemological relations among the concepts. The choice of a language is a matter of convenience. This 'principle of tolerance' is stated in Carnap's second important book *The Logical Syntax of Language* ([1934] 1937). By the logical syntax of a language he means the systematic statement of the formal rules that govern it together with the development of the consequences that follow from the rules.

In the *Aufbau* Carnap defends, like Mach and Russell, the positivist thesis that – in principle – it is possible to reduce all scientific concepts stepwise to (concepts referring to) the immediately given. While Mach lacked the logical theory of relations developed in *Principia Mathematica* and Russell left it in *Our Knowledge of the External World* (1914) at a very readable informal sketch, Carnap uses logic to design a 'constitutive theory' and work it out in some detail. Its main thesis says that it is possible to deduce all scientific concepts by means of 'constitutional definitions' from a few fundamental concepts. When this logical analysis is completed for all concepts, they can be ordered into a 'constitutive system.' At its basis, concepts refer directly to the given; in the next layer they refer to physical objects, then follow other minds and finally the objects of social science. Instead of saying that concepts are constituted he could as well say that objects are constituted. This is merely another mode of speaking.

The Gestalt psychology of Wertheimer, Köhler, and Koffka had shown that simple sense data result from a process of abstraction, while instantaneous visual fields may be given as units. Therefore, Carnap chooses total instantaneous experiences (Elementarerlebnisse) as fundamental elements. They are momentary cross sections of the total stream of experience. At this level the ego has not yet been constituted. Still subjectless fundamental elements are individual (eigenpsychisch). Hence the basis of the system is solipsistic, but this is a methodic, not an ontological solipsism. Carnap's sole fundamental relation is a similarity relation between fundamental elements. In his exposition, a process of definitions starting from recollections of similarities (Ähnlichkeitserinnerungen) between pairs of visual fundamental elements leads first to the visual domain, then to positions in the visual field, to colors, the temporal order, etc. Carnap calls this process 'quasi-analysis.' Next, things in the perceptual space are constructed, among them the observer's body and other persons' bodies. The class of all individual experiences of the observer is his 'ego.' Then follow other minds and finally cultural products. Thus any scientific statement could – in principle – be transformed into a statement on similarity relations between total instantaneous experiences. This construction avoids metaphysical hypostatizations of physical or mental entities. Although statements on bodies and minds remain possible, the body–mind problem has been dissolved.

Later Carnap admitted that a definitional reduction of concepts is not possible and that the extensional language that he proposed is not sufficient. In his article 'Die physikalische Sprache als Universalsprache der Wissenschaft' ([1932a], 1934a, literally: The physicalist language as a universal language of science) Carnap prefers the physicalist language. Now phenomenalist neopositivism has come to an end, but physicalist neoempiricism lives on.

The Basic Thesis of Empiricism

In *General Theory of Knowledge* ([1918]1985), Schlick rejects both Kant's thing-in-itself and Mach's phenomenalism. Instead he proposes a critical realism. He also gives a thorough critique of Kant's synthetic a priori. While Kant believes "When … strict universality belongs to a judgment essentially; this points to a special source of cognition for it, namely a faculty of a priori cognition" (*Critique of Pure Reason*, B4), empiricists take the notion that thinking can lead to factual knowledge out of its own resources without using any empirical material to be a basic error of metaphysics. Only the formal (analytic) truths of logic and mathematics can be known a priori, all factual (synthetic) knowledge is a posteriori. This is the basic thesis of empiricism. In Einstein's words: "As far as the laws of geometry refer to reality, they are not certain; and as far as they are certain, they do not refer to reality."

The Verifiability Criterion of Meaning

The best known proposal of logical positivism is the verifiability criterion of meaning (or meaningfulness). Only if we know what a statement means, can we assess whether it is true. However, the verifiability criterion implies that we can only know what it means, if we can assess whether it is true. Its best known wording by Waismann (1930, 229, my translation) reads as follows: "If it can in no way be indicated when a statement is true, then this statement does not have any meaning at all; for the meaning of a statement is the method of its verification. … A statement which cannot be definitely verified is not verifiable at all; it just lacks any meaning." Waismann's wording presupposes that statements about the empirically given can be definitely verified or are for some reason certain and therefore do not need verification. This presupposition is subject of the debate on protocol sentences.

Serious problems of the verifiability criterion of meaning were evident. First, we could not answer questions, if they had no linguistic meaning. As they are neither true nor false, they cannot be verified. If, however, questions can be meaningful without being verifiable, why can statements not be meaningful without being verifiable? Second, universal statements like 'All ravens are black' cannot be definitely verified because of the problem of induction. Accordingly they are considered meaningless. However, we use them in everyday life, and classical physics is deterministic.

To solve the problem of universal statements, various proposals have been made. They all have their specific defects, and they all have a common defect: not even singular observation statements can be definitely verified, for the properties that they attribute to objects are dispositions to lawlike behavior, but we observe only instances of this behavior. Hence according to the verifiability criterion of meaning there are no meaningful statements at all. Karl Popper (1902–94) thoroughly criticized these proposals in a manuscript that was in 1933 accepted for publication by Schlick and Frank but was rejected by the publisher Springer because of its length. An incomplete edition appeared only in 1979. What Helmholtz had said about dispositions Popper said about disposition predicates: the statement "Here is a glass of water" cannot be

verified, because the universals "… is glass" and "… is water" express lawlike behavior ([1935]1959a, 95), dispositions, and each of these laws transcends experience (424). The verifiability criterion of meaning was soon given up when Popper proposed in his *Logic of Scientific Discovery* a falsifiability (later testability) criterion of demarcation between empirical science and metaphysics, according to which those, and only those, synthetic statements are considered to be empirically scientific that are empirically falsifiable ([1933]1959b, sect. 6). Metaphysical statements may be meaningful but are not scientific.

The Debate on Protocol Sentences

The debate on protocol sentences brought another radical change. Its most important arguments were exchanged in three articles. According to Carnap's 'Die physikalische Sprache als Universalsprache der Wissenschaft' ([1932]1934), protocol sentences like 'here, now, blue; there, red' refer to the given, need no justification, and serve as foundation for all other statements of science. Neurath objects in 'Protocol Sentences' ([1932]1959) that there are no conclusively established protocol sentences. His protocol sentences refer to physical objects and contain the name of a person drafting the protocol, an indication of place and time, and a perception term. They are subject to verification and may be changed or even discarded. In his rejoinder 'On Protocol Sentences' ([1932] 1987) Carnap argues that both phenomenalist and physicalist protocol sentences are possible, but he now prefers an intersubjective, physicalist language. He rejects Neurath's proposal to admit only protocol sentences of a certain form in favor of Popper's proposal that every concrete sentence of the physicalist language of science can – under certain circumstances – serve as a protocol sentence. All sentences are fallible and must be empirically tested. As there are no absolute initial sentences of science left, Popper's testing procedure (in [1933] 1959b) involves, according to Carnap, the most radical elimination of the absolutism of the given. This ends the debate on protocol sentences, while the rise of Popper's critical rationalism, an advanced version of neoempiricism, begins.

The quest for certainty is not yet over. Schlick never was a phenomenalist, but he still clings to the absolutism of the given. According to him, understanding and verifying coincide in the case of 'confirmations' (Konstatierungen) like 'Here now so and so' ([1933]1959, 221, 224). 'Confirmations' are absolutely true and certain. On the other hand, they are only subjective, and their function lies only in the immediate present. Accordingly, they play only a pragmatic part in the evaluation of scientific hypotheses.

The Duhem-Quine Thesis

The Duhem-Quine thesis is the most serious attack on neoempiricism. According to Willard Van Orman Quine (1908–2000), modern empiricism has been conditioned in large part by two dogmas (1951). One is the analytic/synthetic distinction; the other is reductionism, the belief that each meaningful statement is translatable into a statement about immediate experience. Both are ill-founded. If they are given up, the border between science and metaphysics falls and the philosophy of science shifts toward pragmatism.

Quine calls a statement 'analytic' if it is true by virtue of meaning alone. Now there is no precise meaning of 'meaning.' Moreover, we cannot in all languages give the word 'analytic' a precise meaning. Therefore, he concludes, the analytic/synthetic distinction is not tenable. However, Quine's argument is not conclusive. Tautologies have no meaning; they are analytic because of their form alone, explicit definitions create new synonymies, any author can state which of his sentences are meant to be linguistic conventions, and it would be sufficient to give the word 'analytic' a precise meaning only for that language whose statements we are actually examining.

According to Quine the reductionism of Carnap's *Aufbau* survives in the idea that statements can be tested separately. While Duhem had argued that we never test a single physical theory but always test the whole of physics, Quine argues that we always test the whole of our knowledge including pure mathematics and logic. We can hold true any statement come what may, if we make drastic enough adjustments elsewhere in the system of our knowledge, even among logical laws. This argument is even less conclusive. Laws of logic and mathematics are true or false according to their form, while laws of physics fit or do not fit reality. Only if we had reasons to accept Quine's (and Mill's) pragmatist or instrumentalist interpretation of both kinds of laws, could it seem reasonable to reject the analytic/synthetic distinction. Even though not conclusive the holism of the Duhem-Quine thesis is the best known trigger of the pragmatist turn in analytic philosophy.

Prospects

Phenomenalist neopositivism ended in the 1930s. Neoempiricists have not only given up the idea that metaphysical statements are literally meaningless but also admit that there is no sharp boundary between science and metaphysics. They recognize that most scientific theories are not from the beginning empirically testable but start as metaphysical hypotheses in the sense of Popper's criterion of demarcation and become scientific, i.e., empirically testable, only after some development of the theories themselves or of the means of testing them. Before the thesis of the Higgs-boson's existence – possibly – became testable, scientists had to specify which traces it would leave and the Large Hadron Collider had to be built.

There is still a difference between scientific speculation, which aims at testable hypotheses, and philosophical speculation, whose results never become intersubjectively testable, and there are differences between philosophical speculations. In his 1929 lecture '*Was ist Metaphysik?*' Martin Heidegger pronounced that the nothing (or nothingness) nothings and that this activity is the origin of negation. Carnap diagnosed that Heidegger had turned the negation 'nicht' (not) both into a substantive 'das Nichts' (the nothing or nothingness) and into a verb 'nichten' (to nothing) and that his pronouncement was therefore nonsensical. Immanuel Kant asserted in *Critique of Pure Reason* that (Euclidian) space is an a priori intuition, a necessary presupposition of empirical knowledge. However, according to Einstein's general theory of relativity physical space is elliptic and visual space is taken to be by and large hyperbolic. Does this mean that what Kant considered a priori necessarily true has turned out a posteriori to be factually false?

Did Kant mean a third kind of space, and what can be said about it other than that it is Euclidian? Kant's theses on the contribution of categories and of the a priori intuitions of space and time to our knowledge filled a gap that phenomenalist empiricism had left. Insofar they furthered the evolution of epistemology, even though they turned out to be untenable.

Neoempiricists will rather trust in Helmholtz's critical realism than in Kant's transcendental idealism and learn from psychology of perception, neurophysiology, and – possibly – electronic modeling of brain processes. As these disciplines develop, so will empiricism. Again and again new aspects of modern empiricism will be debated. On the other hand, two issues have long been disputed, sometimes bitterly: the methodological unity of science and the possibility of cognitive ethics.

There is empirical research in the humanities, but there are still authors claiming to know methods peculiar to the humanities. Neoempiricists will accept any way to discovery, whether it is methodical or not, but they will insist that all results remain hypothetical and must in the end be intersubjectively tested, i.e., by means of our physiological senses. Insofar they uphold the idea of the methodological unity of science. Their opponents will insist that they know methods of evaluating results of the humanities that do not involve sensory experience but are nevertheless intersubjective among the knowing, and part of them will even call these methods empirical because they involve a different kind of experience.

Since antiquity, countless attempts have been made to show that there is ethical knowledge, that we can know what is objectively virtuous, good, or right. Up to now, none of them has withstood serious criticism. Nevertheless, the claim to possess ethical knowledge, religious or temporal, has proved to be an efficient means of influencing people. Open criticism tends to reduce its efficiency and is therefore much resented. In the dispute with the skeptic a derogatory label can be an efficient weapon. So the skeptical, neoempiricist is often called a 'positivist,' suggesting that his judgment is unreliable because he still maintains a position that has long been refuted. Others may call him an 'infidel.' Probably, the dispute about ethical knowledge will never end.

Logics for Knowledge Representation

Bernhard Nebel, Institut für Informatik, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Knowledge representation (*see* Knowledge Representation) and reasoning plays a central role in Artificial Intelligence. Research in Artificial Intelligence (henceforth AI) started off by trying to identify the *general mechanisms* responsible for intelligent behavior. However, it quickly became obvious that general and powerful methods are not enough to get the desired result, namely, intelligent behavior. Almost all tasks a human can perform which are considered to require intelligence are also based on a huge amount of knowledge. For instance, understanding and producing natural language heavily relies on knowledge about the language, about the structure of the world, about social relationships, and so on (*see* Logic and Linguistics).

One way to address the problem of representing knowledge and reasoning about it is to use some form of logic. While this seems to be a natural choice, it took a while before this 'logical point of view' became the prevalent approach in the area of knowledge representation. Below, we will give a brief sketch of how the field of knowledge representation evolved and what kind of logical methods have been used. In particular, we will argue that the important point about using formal logic is the *logical method*.

Logic-Based Knowledge Representation: A Historical Account

McCarthy (1968) stated very early on that mathematical, formal logic appears to be a promising tool for achieving human-level intelligence on computers. However, in the early days of AI, there were also a number of researchers with a completely different opinion. Minsky (1975), for example, argued that knowledge representation formalisms should be flexible and informal. Moreover, he argued that the logical notions of *correctness* and *completeness* are inappropriate in a knowledge representation context.

While in those days heated arguments of the suitability of logic were exchanged, by the end of the 1980s, the logical perspective seem to have gained the upper hand (Brachman, 1990). Since the 1990s almost all research in the area of knowledge representation and reasoning was based on formal, logical methods as demonstrated by the papers published in the biannual international conference on *Principles of Knowledge Representation and Reasoning*, which started in 1989.

It should be noted, however, that two perspectives on logic are possible. The first perspective, taken by McCarthy (1968), is that logic should be used to *represent* knowledge. That is, we use logic as the representational and reasoning tool inside the computer. Newell (1982) on the other hand proposed in his seminal paper on the *knowledge level* to use logic as a formal tool to *analyze* knowledge. Of course, these two views are not incompatible. Furthermore, once we accept that formal logic should be used as a tool for analyzing knowledge, this could also lead to using logic for representing knowledge and for reasoning about it as well.

Knowledge Representation Formalisms and Their Semantics

Saying that logic is used as the main formal tool does not say which kind of logic is used. In fact, a large variety of logics (Gabbay et al., 1995) have been employed or developed to solve knowledge representation and reasoning problems. Often, one started with a vaguely specified problem, developed some kind of knowledge representation formalism without a formal semantics, and only later started to provide a formal semantics. Using this semantics, one could then analyze the complexity of the reasoning problems and develop sound and complete reasoning algorithms (*see* Algorithm). I will call this the *logical method*, which proved to be very fruitful in the past and has a lot of potential for the future.

One good example for the evolution of knowledge representation formalisms is the development of *description logics*, which have their roots in so-called *structured inheritance networks* formalisms such as KL-ONE (Brachman, 1979). These networks were originally developed in order to represent word meanings. A *concept node* connects to other concept nodes using *roles*. Moreover, the roles could be structured as well. These networks permit, for example, the definition of the concept of a bachelor.

Later on, these structured inheritance networks were formalized as so-called *concept languages*, *terminological logics*, or *description logics*. Concepts were interpreted as unary predicates, roles as binary relations, and the connections between nodes as so-called *value restrictions*. This leads for most such description logics to a particular fragment of *first-order predicate logic*, namely, the fragment L_2. In this fragment only two different variable symbols are used. As it turns out, this is a *decidable fragment* of first-order logic.

However, some of the more involved description logics go beyond L_2. They contain, for example, relational composition or transitive closure. As it turns out, such description logics can be understood as variants of multimodal logics (Schild, 1991), and decidability and complexity results from these multimodal logics carry over to the description logics.

All these insights, that is, determination of decidability and complexity as well as the design of decision algorithms, are based on the rigorous formalization of the initial ideas (Baader et al., 2003). In particular, it is not just one logic that is used to derive these results, but it is the *logical method* that

led to the success. One starts with a specification of how expressions of the language or formalism have to be interpreted in formal terms. Based on that one can specify when a set of formulae is *satisfiable*, that is, describes structures. Based on that, *decidability* and *complexity* (*see* Algorithm) – perhaps of fragments of the languages – can be determined. In parallel, one can design inference methods or decision procedures that enable us to determine *satisfiability* of a formula on purely syntactic grounds. Finally, one can then prove these methods to be *correct* and *complete*.

Based on these formal foundations, description logics have made it into the 'real life.' Meanwhile they have become the formal foundation for the *semantic web* and the *web ontology language* (Antoniou and van Harmelen, 2004).

Nonmonotonic Logics

Another interesting area where the logical method has been applied is the development of so-called *nonmonotonic logics* (*see* Nonstandard Reasoning). These are based on the intuition that sometimes a logical consequence should be retracted if new evidence becomes known. For example, we may assume that our car will not be moved by somebody else after we have parked it. However, if new information becomes known, such as the fact that the car is not at the place where we have parked it, we are ready to drop the assumption that our car has not been moved.

This general reasoning pattern was used quite regularly in early AI systems, but it took a while before it was analyzed from a logical point of view. In 1980, a special issue of the *Artificial Intelligence* journal appeared, presenting different approaches to nonmonotonic reasoning, in particular Reiter's (1980) *default logic* and McCarthy's (1980) *circumscription* approach.

A disappointing fact about nonmonotonic logics appeared to be that it is very difficult to formalize a domain such that one gets the intended conclusions. In particular, in the area of *reasoning about actions*, McDermott (1987) has demonstrated that the straightforward formalization of an easy temporal projection problem (the 'Yale shooting problem') does not lead to the desired consequences. However, it is possible to get around this problem. Meanwhile, the formalization of dynamic domains is based either on an approach using the *situation calculus* using so-called *successor-state-axioms* (Reiter, 2001) or they are based on *action languages* using the semantics of state transition systems (Gelfond and Lifschitz, 1993).

It took more than a decade before people started to analyze the computational complexity (of the propositional versions) of these logics. As it turned out, these logics are usually somewhat more difficult than ordinary propositional logic (Gottlob, 1992). This, however, seems tolerable since we get much more conclusions than in standard propositional logic. At the same time, the tight connection between nonmonotonic logic and *belief revision* (Gardenfors, 1988) was noticed. Belief revision – modeling the evolution of beliefs over time – is just one way to describe how the set of nonmonotonic consequences evolve over time, which leads to a very tight connection on the formal level for these two forms of nonmonotonicity (Nebel, 1991). Again, all these results and insights are mainly based on the logical method to knowledge representation.

One of the important results on the research of nonmonotonic logics is *answer set programming* (ASP) (Martin Gebser et al., 2012), which is based on the stable model semantics of *logic programming*. This kind of logic programming allows for straightforward formulations of many *search and optimization problems* and is very efficient in computing the solutions to such problems in practice.

Qualitative Spatial and Temporal Representation and Reasoning

The formalization of knowledge about qualitative aspects of space and time is an area that reaches from philosophical logic over AI to psychology. Again, the logical method is prevalent here, as, for example, demonstrated by the handbook on spatial logics (Aiello et al., 2007).

The development of this area started probably with Allen's (1983) paper about the formalization of qualitative interval relations. With this formalization one could express the relative position of one-dimensional objects, which were interpreted as time intervals. This so-called *Allen calculus* was intensively analyzed, in particular from a computational complexity point of view (Nebel and Bürckert, 1995), and led to the development of a number of similar calculi for different aspects of spatial relations, for example, the RCC-8 calculus (Randell et al., 1992). For most of these calculi symbolic constraint-propagation methods (*see* Constraint-Satisfaction Models) are employed to address the above-mentioned satisfiability problem (Renz and Nebel, 2007). However, as it turns out, these inference methods are often not complete.

Using the Logical Method in Cognitive Science

While in general Artificial Intelligence and Cognitive Science have a lot in common, the general research goals are usually quite distinct. Artificial Intelligence focuses on synthesizing intelligent systems, Cognitive Science concentrates on analyzing human cognition. Nevertheless, there are often points where these two disciplines can help each other.

In particular in the area of *spatial cognition*, the logical analysis of temporal and spatial concepts was quite successful. In particular, Allen's temporal relations interpreted as one-dimensional spatial relations were in the focus of attention. Based on an analysis of how many possible configurations arise when composing two interval relations, experiments showed that humans systematically preferred only one particular subset of the possible relations. Here the logical formalization was used to provide the normative result against which the observed behavior could be compared. Furthermore, systematic deviations could be correlated to the number of possible configurations and to the subset of what has been termed preferred relations (Knauff et al., 1998). Similar results were achieved with respect to RCC-8 (Renz et al., 2000).

Outlook

The above description of the use of logics for knowledge representation is necessarily incomplete. Nevertheless, one should have got an idea of how logics are used in the area of

knowledge representation. As mentioned, it is the idea of providing knowledge representation formalisms with formal (logical) semantics that enables us to communicate their meaning, to analyze their formal properties, to determine their computational complexity, and to devise reasoning algorithms.

While the research area of knowledge representation is dominated by the logical approach, this does not mean that all approaches to knowledge representation must be based on logic. Probabilistic, decision theoretic, and game theoretic approaches have become quite popular. However, even here, the *logical method* prevails. For example, Lutz and Schröder (2010) combine in their approach description logics with probability theory to model subjective uncertainty.

Log-Linear and Marginal Models

Tamás Rudas, Faculty of Social Sciences, Eötvös Loránd University, Budapest, Hungary

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Log-linear models for the joint distribution of several categorical variables assume that the cell frequencies or probabilities are influenced by multiplicative effects associated with groups of variables. These effects are conditional on the remaining variables in the analysis. Marginal log-linear models provide more flexibility, by allowing some of the effects to depend only on subsets of variables. These models have important applications in social mobility, longitudinal data or causal analysis, and are the basis of doing regression analysis and graphical modeling for categorical variables. This article reviews several of the reasons why log-linear models are considered, discusses the interpretation of such models and of the related parameters, introduces marginal log-linear models, and describes several of the areas of application.

Log-Linear Models

Any model class used in statistical analysis aims to provide simple structure to ease interpretation and flexibility to provide good fit to data. While model fit to data is usually considered a technical issue (although there are some ad-hoc suggestions), the perception of simplicity is often influenced by conventions, education, and trends. The class of log-linear models may be looked at in a number of different ways, each providing a different aspect of simplicity, and a possibility for interpretation.

Log-linear models apply to the joint analysis of several categorical (discrete) variables, where the data take the form of observed counts, usually presented as entries in the cells of a contingency table. The goal of the analysis, broadly speaking, is to find structure behind the population probabilities or population frequencies.

For many researchers, linear (more precisely: additive) effects appear simple, but these are difficult to confine to (0, 1), where probabilities are, so one possible idea is to assume that the logarithms of the cell probabilities are sums of certain effects. For example, if p_{ij} is the probability in the cell defined as the combination of the ith category of the first variable and the jth category of the second variable, if there are two variables only, one may assume that

$$log\, p_{ij} = a + b_i + c_j \qquad [1]$$

where a is the overall effect, present in every cell, b_i is the effect of the ith category of the first variable (often called the effect of the ith row of the contingency table) and c_j is the effect of the jth category of the second variable (often thought of as the effect of the jth column of the contingency table). The formula in [1] is analogous to the model of no interaction in a two-way analysis of variance. The formula in [1] can be easily rewritten as

$$log\, p_{ij} = d_i + e_j \qquad [2]$$

and the model remains the same. One might think that a more restrictive assumption is that the row and column effects are linked to the row and column marginal probabilities as

$$d_i = log\, p_{i+},\ e_j = log\, p_{+j}$$

giving

$$log\, p_{ij} = log\, p_{i+} + log\, p_{+j} \qquad [3]$$

which, after exponentiating gives

$$p_{ij} = p_{i+}p_{+j} \qquad [4]$$

that is, the well known independence model. In fact, [3] or [4] which are equivalent, if the probabilities are assumed to be positive, are not more restrictive than [1] or [2], rather they are equivalent.

Formula [4] may also be seen as linking the joint distribution p_{ij} to its own one-dimensional marginal distributions. One may also ask the following question. Out of all the two-dimensional distributions having the one-way marginal distributions p_{i+} and p_{+j}, which one is the closest to uniform, that is, which one contains the least amount of information, in addition to the one-way marginals. The answer is the distribution of the form [4].

It is immediate from [4], that the odds ratio (for simplicity of presentation, thinking only of the case when both variables are binary) is also equal to 1:

$$OR = \frac{p_{11}p_{22}}{p_{12}p_{21}} = 1 \qquad [5]$$

and it can be seen that [5] also implies [4].

These are four different aspects (see Goodman, 1970; Bishop et al., 1975; Haberman, 1978; Gokhale and Kullback, 1978; Rudas, 1998), which all point to the same model, and the interpretations of the log-linear model implied by these properties, extend to the general log-linear model.

In general, the log-linear model is defined by choosing a class of subsets of variables, say $\Gamma = \{\gamma_1, \gamma_2, \ldots, \gamma_k\}$ and assuming that in every cell ω of the contingency table, the cell probability $p(\omega)$ may be written as.

$$log\, p(\omega) = \sum_{\gamma_h \in \Gamma} f_{\gamma_h}(\omega_{\gamma_h})$$

where the functions f_{γ_h} depend on the cell ω through the indices of the variables, which are in γ_h. For instance, in the case of [1], the variables are, say, A and B, $k = 3$, $\gamma_1 = \varnothing$, $\gamma_2 = A$, $\gamma_3 = B$, and

$$f_{\gamma_1} = a,\ f_{\gamma_2}(i) = b_i,\ f_{\gamma_3}(j) = c_j$$

The values of the functions f_{γ_h} are called the log-linear parameters, and they are not uniquely defined. One way to make them unique, is to assume that the values of the parameter $f_{\gamma_h}(\omega_{\gamma_h})$ sum to zero, when summed in any of the indices of the variables in γ_h. In this case, the parameters are usually denoted as

$$\lambda_{\gamma_h}(\omega_{\gamma_h})$$

Another important way to make the parameters unique, is to choose a reference category from among all the categories of every variable, and to assume the parameter is zero, whenever ω_{γ_h} is such that any of the variables in γ_h is equal to its reference category. In this case, the parameters are usually denoted as.

$$\mu(\omega_{\gamma_h})$$

For several variables, each of the above properties may be used as a basis of generalization. For example, in the case of three variables, A, B and C, a very important model is conditional independence of A and B, given C. This may be written using $\Gamma = \{\varnothing, A, B, C, AC, BC\}$, as

$$log\ p_{ijk} = f_{\varnothing} + f_A(i) + f_B(j) + f_C(k) + f_{AC}(i,k) + f_{BC}(j,k)$$

With reparameterization, the first four terms may be omitted, and also the model may be written as

$$p_{ijk} = \frac{p_{i+k}p_{+jk}}{p_{++k}}$$

as if one had $\Gamma = \{C, AC, BC\}$, or with a conditional odds ratio as

$$COR(A,B|C=k) = \frac{p_{11k}p_{22k}}{p_{12k}p_{21k}} = 1 \qquad [6]$$

A variant of the most general definition of log-linear models (cf Rudas, 1998) is that given a class of subsets of the variables (the so-called maximal interactions) Γ, if a subset of variables is contained in, for some γ_h, then these variables may be associated, but if no γ_h contains this subset, then these variables, conditioned on all other variables, are not associated. Not associated defined here using generalizations of the conditional odds ratio in [6]. The odds ratio is defined for several variables in a recursive way. For three variables,

$$OR(A,B,C) = \frac{COR(A,B|C=1)}{COR(A,B|C=2)} = \frac{p_{111}p_{221}p_{122}p_{212}}{p_{121}p_{211}p_{112}p_{222}}$$

For example, in the case of three variables, if the maximal interactions are AB, AC, and BC, then there is no association among all three variables, but there may be association among any pair of the variables. In particular setups, more straightforward interpretations are available. When the variables are not binary, a bit more elaborated definition is applied.

Applications and Interpretations of Log-Linear Models

Every log-linear model (or a distribution in a log-linear model) may be interpreted using vanishing higher order interactions. There are two very important applications of log-linear models, where a more specific interpretation is also possible. These are presented next.

Regression for Categorical Variables

In a regression type statistical problem, one of the variables is designated to be a response to the other, explanatory, variables. In the traditional setup when all variables are numerical, very often a linear effect on the expectation of the response is assumed, and when the variables have a joint normal distribution, the ordinary least squares estimation technique has many optimality properties. Such an approach is clearly not appropriate when the variables are categorical. In these cases, the best approach is to fit a log-linear model and use this to obtain a simple formula for the dependence of the conditional odds for the response variable, given the explanatory variables.

For example, out of three variables, let A be response, B and C explanatory. Also assume for simplicity, that A is binary. If the model AB, AC, BC is used, then the multiplicative form of this model, using λ parameters and $\beta = \exp\lambda$, is that

$$p_{ijk} = \beta_{\varnothing}\beta_A(i)\beta_B(j)\beta_C(k)\beta_{AB}(i,j)\beta_{AC}(i,k)\beta_{BC}(j,k)$$

Then, the conditional odds of $A=1$ versus $A=2$ may be written as

$$\frac{p_{1jk}}{p_{2jk}} = \frac{\beta_{\varnothing}\beta_A(1)\beta_B(j)\beta_C(k)\beta_{AB}(1,j)\beta_{AC}(1,k)\beta_{BC}(j,k)}{\beta_{\varnothing}\beta_A(2)\beta_B(j)\beta_C(k)\beta_{AB}(2,j)\beta_{AC}(2,k)\beta_{BC}(j,k)}$$

which simplifies to

$$\frac{p_{1jk}}{p_{2jk}} = \frac{\beta_A(1)\beta_{AB}(1,j)\beta_{AC}(1,k)}{\beta_A(2)\beta_{AB}(2,j)\beta_{AC}(2,k)} = \frac{\beta_A(1)}{\beta_A(2)}\ \frac{\beta_{AB}(1,j)}{\beta_{AB}(2,j)}\ \frac{\beta_{AC}(1,k)}{\beta_{AC}(2,k)}$$

The three terms in the last formula may be identified with the overall odds of $A=1$ versus $A=2$ and how $B=J$ and $C=K$ modify this odds. Under the model AB, AC, BC, the effects of B and C on A can be separated. The farther is the value of $\beta_{AB}(1,j)/\beta_{AB}(2,j)$ from 1, the stronger is the effect of $B=j$ on the conditional odds, and similarly for the other effects.

If, however, the AB, AC, BC model cannot be assumed to describe the population, then one has to work with the model specified by ABC, which means no restriction, and then one would have

$$\frac{p_{1jk}}{p_{2jk}} = \frac{\beta_A(1)}{\beta_A(2)}\ \frac{\beta_{AB}(1,j)}{\beta_{AB}(2,j)}\ \frac{\beta_{AC}(1,k)}{\beta_{AC}(2,k)}\ \frac{\beta_{ABC}(1,j,k)}{\beta_{ABC}(2,j,k)}$$

where the last term is the joint effect of B and C on (the odds of) A, when $B=j$ and $C=k$, which is there in addition to their individual (separable) effects.

For four variables, the model AB, ACD, BCD means that out of the three explanatory variables, B has a separable effect, and C and D also have a joint effect on A. Or AB, AC, BCD means that D does not have a direct effect on A.

This approach gives clear meaning of and answer to the questions of which out of the potential explanatory variables have effects, how strong are the existing effects and whether there are joint effects, in addition to the individual effects.

Markov Models

Many, but not all, of the log-linear models may be interpreted using conditional independences. One criterion that may be

used to decide whether or not the log-linear model specified by Γ has this property is the following one. The log-linear model may be interpreted using conditional independences, if and only if Γ does not have a forbidden configuration. A forbidden configuration is a subset of variables γ, such that Γ does not contain γ, but it does contain all proper subsets of it. To check the latter property, Γ needs to be completed with all subsets of the interactions in it, which does not affect the model, only its parameterization. For example, $\Gamma = \{AB, AC, BC\}$ has a forbidden configuration, namely ABC, $\Gamma = \{AB, AC, ABC\}$ does not have one.

The conditional independence properties, also called Markov properties, have many variants. The simplest one, called the pairwise Markov property, is that if variables A and B are not contained in any interaction of the model, then A and B are conditionally independent given all other variables.

Log-linear models that do not have a forbidden configuration are called graphical models, because they can be well-represented by graphs. The nodes of such a graph are the variables, and two nodes are connected if and only if there is an interaction in the model, which contains these two variables. For example, in the case of the model defined by $\Gamma = \{AC, BC\}$, the nodes A and C and the nodes B and C are connected, but A and B are not connected. Such a graph represents (or many of us have learned to see that way) the essence of conditional independence between A and B, given C: there may be direct relationships between A and C and between B and C, but A and B are not directly related, rather only through C. In general, according to the Markov property, two variables are conditionally independent, given all other variables, if and only if they are not connected by an edge. It has to be emphasized, that the graph is primarily a tool to communicate assumptions defining a statistical model: it has no inherent conditional independence meaning, rather one is associated with it in the graphical modeling framework. In the linear structural equations tradition, a fundamentally different interpretation is associated with a graph.

Other Markov properties, which are equivalent to the local one under the assumption that all cell probabilities are positive, are the local and the global Markov properties, see Lauritzen (1996) or Edwards (2000). The former property says that a variable and those to which it is not connected, are conditionally independent, given those, to which it is connected. The latter one says, that if three disjoint groups of variables are such, that all paths connecting a variable in the first one with a variable in the second one, goes through a variable in the third one, then the first and second groups of variables are conditionally independent given the third group of variables.

An important property of graphical Markov models is that they apply, not only to categorical variables, but to Gaussian variables, as well, and even to situations, when some of the variables are categorical, and the conditional distribution of the other variables, given the categorical ones, is Gaussian. Edwards (2000) and Whittaker (2009) contain several interesting examples of using graphical Markov models.

Estimation and Testing

In the context of log-linear models, testing of model fit is almost always based on comparing observed and estimated frequencies. The estimated frequencies are usually determined based on the principle of maximum likelihood. When all observed cell frequencies are positive, there is a unique maximum likelihood estimate of the cell probabilities, whether sampling was multinomial or Poisson. These estimates may be obtained by the Iterative Proportional Fitting algorithm.

The maximum likelihood estimates under a log-linear model determined by the interactions $\Gamma = \{\gamma_1, \gamma_2, \ldots, \gamma_k\}$ are uniquely characterized by the following two properties:

The conditional odds ratios of the variables γ, given any categories of all other variables, are equal to 1, if γ is not a subset of any γ_h and the marginal distributions of the variables γ are equal to their observed distributions, if γ is a subset of any γ_h.

In other words, the observed distributions of the interactions are preserved by the maximum likelihood estimate (MLE), and are combined with the no higher order interaction property defining the log-linear model. That is, the MLE is the most uniform distribution out of those that have the observed marginal distributions of the subsets of variables, which are allowed interactions.

The comparison of the observed and estimated frequencies is usually done by test statistics with an asymptotic chi-squared distribution (Read and Cressie, 2011). The application of those test statistics is known to be limited to sample sizes relatively large compared to the size of the contingency table, see, e.g., Rudas (1986) and in case of doubt, resampling methods should be used.

The log-linear parameters computed from the MLE are the maximum likelihood estimates of the true parameters and may be used in analyses like the one described in Section Regression for Categorical Variables.

Marginal Models

Marginal models generalize log-linear models, providing larger flexibility in modeling. Log-linear models restrict the association among certain variables, conditioned on the categories of all other variables. Conditioning is one way to reduce the number of variables involved in the analysis. Conditioning means selection: the analysis is confined to the cases which are in the specified categories of the conditioning variables. Another way to reduce the number of variables involved in the analysis is marginalization. Some of the variables are omitted from consideration. Several statistical applications involve marginalizing, before conditional associations could be considered. For such examples, see Bergsma et al. (2009, 2013) and Rudas and Bergsma (2004).

One approach, initiated in Bergsma and Rudas (2002), is based on defining a parameterization of all distributions using marginal log-linear parameters, and then imposing restrictions by setting some of these parameters equal to zero. A marginal log-linear parameter is a log-linear parameter, which is computed from a marginal distribution of the table. For

instance, assume that A and B are independent, and also B and C are independent, but these independences are meant to be marginal, i.e., to hold when the third variable is disregarded. Then, one may consider the AB, BC, ABC marginals of the table (the last marginal always has to be the entire table). Then the following log-linear parameters are considered:

$$\text{In the marginal } AB\text{: } \lambda_{\varnothing}^{AB}, \lambda_{A}^{AB}(i), \lambda_{B}^{AB}(j), \lambda_{AB}^{AB}(i,j)$$

$$\text{In the marginal } BC\text{: } \lambda_{C}^{BC}(k), \lambda_{BC}^{BC}(j,k)$$

$$\text{In the marginal } ABC\text{: } \lambda_{AC}^{ABC}(i,k), \lambda_{ABC}^{ABC}(i,j,k)$$

that is, in every marginal, the log-linear parameters of those interaction are computed, which have not been computed in previous marginals. The advantage of this parameterization is that the required marginal independences may now be imposed by assuming that

$$\lambda_{AB}^{AB}(i,j) = 0 \text{ and } \lambda_{BC}^{BC}(j,k) = 0$$

The above approach may always be applied, when the marginals of interest (AB and BC in the example), may be ordered in such a way, that no smaller marginal comes after a larger one. When there is only one marginal of interest, the entire table, i.e., no marginalization is involved, one obtains from this approach the standard log-linear models.

Estimation and testing of marginal log-linear models are quite well understood, and for the user, they are not more complex than the same procedures are for standard log-linear models. In general, the marginal log-linear parameters, which are not set to zero are estimated and interpreted.

In the above example, the value of $\lambda_{AC}^{ABC}(i,k)$ is a measure of how strong is the association between variables A and C, given the categories of B (in fact, the parameter gives the average value for the different categories of B), and $\lambda_{ABC}^{ABC}(i,j,k)$ is a measure of the second-order association among the three variables. If, however, interest lied in estimating the strength of marginal (as opposed to conditional) interaction between A and C, under the same model, one could use the marginals AB, AC, BC, ABC, and could parameterize as follows:

$$\text{In the marginal } AB\text{: } \lambda_{\varnothing}^{AB}, \lambda_{A}^{AB}(i), \lambda_{B}^{AB}(j), \lambda_{AB}^{AB}(i,j)$$

$$\text{In the marginal } AC\text{: } \lambda_{C}^{AC}(k), \lambda_{AC}^{AC}(i,k)$$

$$\text{In the marginal } BC\text{: } \lambda_{BC}^{BC}(j,k)$$

$$\text{In the marginal } ABC\text{: } \lambda_{ABC}^{ABC}(i,j,k)$$

The model would be defined by the same assumptions, but one would get an estimate for the strength of the marginal association between A and C from $\lambda_{AC}^{AC}(i,k)$.

Applications of Marginal Models

As the foregoing example illustrates, the marginal log-linear modeling approach is quite flexible both in model definition and in the parameters used. Next, some applications relevant in the social sciences are discussed. For several other examples, see Bergsma et al. (2009), Rudas and Bergsma (2004), and Németh and Rudas (2013a).

Panel Studies

In panel studies, the same individuals are observed repeatedly, for example, they are interviewed about their political party preferences, or their television viewing behavior is recorded. The main advantage of such designs is that transitions may be observed and analyzed. For example, how supporters of a given political party change their preferences over time or where the current supporters of a political party came from. The model of interest is often that of a Markov chain. For instance, a one-step Markov chain assumes that past positions influence the current position only through the immediate past position. More precisely, the assumption is that the conditional probabilities of the different categories of the current position, when conditioned on the previous position, do not change upon further conditioning on earlier positions. If the variable observed in time point t is denoted as A_t, the assumption is that

$$A_t \text{ is conditionally independent from } A_{t-2}, A_{t-3}, \ldots, A_1, \text{ given } A_{t-1}$$

for all time points t. If there are, say six time points, the assumptions are

$$A_3 \text{ is conditionally independent from } A_1, \text{ given } A_2$$

$$A_4 \text{ is conditionally independent from } A_2, A_1, \text{ given } A_3$$

$$A_5 \text{ is conditionally independent from } A_3, A_2, A_1, \text{ given } A_4$$

$$A_6 \text{ is conditionally independent from } A_4, A_3, A_2, A_1, \text{ given } A_5$$

and the relevant marginal log-linear parameterization is obtained using the marginals

$$A_1A_2A_3, \quad A_1A_2A_3A_4, \quad A_1A_2A_3A_4A_5, \quad A_1A_2A_3A_4A_5A_6$$

The rule to impose the required conditional independences is to set every marginal log-linear parameter to zero, which contains variables that are assumed to be conditionally independent from each other. For example, in the $A_2A_2A_3A_4$ marginal, the following log-linear parameters are used in the parameterization (the indices are omitted):

$$\lambda_{A_4}^{A_1A_2A_3A_4}, \lambda_{A_1A_4}^{A_1A_2A_3A_4}, \lambda_{A_2A_4}^{A_1A_2A_3A_4}, \lambda_{A_3A_4}^{A_1A_2A_3A_4}, \lambda_{A_1A_2A_4}^{A_1A_2A_3A_4}, \lambda_{A_1A_3A_4}^{A_1A_2A_3A_4},$$
$$\lambda_{A_2A_3A_4}^{A_1A_2A_3A_4}, \lambda_{A_1A_2A_3A_4}^{A_1A_2A_3A_4}$$

Note that interactions involving only the first three variables are parameterized in the previous marginal. The conditional independence involving the first four variables is imposed by assuming that

$$\lambda_{A_1A_4}^{A_1A_2A_3A_4} = 0, \lambda_{A_2A_4}^{A_1A_2A_3A_4} = 0, \lambda_{A_1A_2A_4}^{A_1A_2A_3A_4} = 0, \lambda_{A_1A_3A_4}^{A_1A_2A_3A_4} = 0,$$
$$\lambda_{A_2A_3A_4}^{A_1A_2A_3A_4} = 0, \lambda_{A_1A_2A_3A_4}^{A_1A_2A_3A_4} = 0$$

The parameters not set to zero are estimated from the data and model fit is tested. If the model is not rejected, the estimated values of $\lambda_{A_3A_4}^{A_1A_2A_3A_4}$ provide information for

the effect of the position at time point 3, on the position at time point 4.

In fact, panel studies may be seen as repeated measurements, where variables are measured before and after a treatment, with treatment being the events that occurred in between two measurements. In another repeated measurement setup, one may be interested in whether or not brand preferences are altered as a result of information regarding the physiological effects of the consumption of certain products. In an experiment, subjects are interviewed about their brand preferences, then they study information related to the effects of consumption, then they are interviewed again. Let C be a covariate (like income categories), and B_b and B_a. The declared brand preferences before and after the treatment was applied. Then, the assumption of the brand preference being independent from the covariate, both before and after the treatment, is exactly the first model discussed in Section Marginal Models: B_b and C are independent and also B_a and C are independent.

Directed Markov Models

Currently, much research interest is concentrated around models describing effects among variables, be these casual or evidential. Such models are discussed under various names in the literature, including directed Markov models, directed graphical models, DAG models, Bayesian networks. The assumptions in these models may also be formulated as conditional independences, i.e., Markov properties, but these take into account the direction in which the assumed effects go.

The graphs that are often used to illustrate or communicate such models are directed, which means that two nodes, representing two variables, if connected, are connected by an arrow, the direction of which shows the direction of the effect. The graphs are, further, acyclic, which means that it is not possible to start in a node, follow the direction of the arrows, and return into this node (directed acyclic graph = DAG). In a DAG, the parents of a node are those nodes, from which an arrow points to this node. The nondescendants of a node are those nodes, into which one may not arrive from this node, following the direction of the arrows. Parents of a node are all nondescendants of it, otherwise the graph would not be acyclic.

The conditional independence property associated with a DAG, the directed Markov property is that every node is conditionally independent from its nondescendants, which are not parents of it, given its parents.

For example, the Markov chain discussed in Section Panel Studies may also be described by a DAG, if one draws an arrow from A_t to A_{t+1}, for all time points t, and the directed Markov property coincides with the Markov property discussed in Section Panel Studies, and the parameterization and interpretation using marginal log-linear models also applies.

In fact, every directed Markov model is a marginal log-linear model (see Rudas and Bergsma, 2004 or Németh and Rudas, 2013a) and the estimated values of the marginal log-linear parameters may be used to assess the magnitude of effects suggested by the data, after appropriate model testing. There are several areas in social and behavioral research, where DAG models describe relevant substantive hypotheses. Németh and Rudas (2013a,b) apply marginal models for the analysis of the social status attainment process in various setups, and give detailed description of interpretations and computations, using DAG and some other related models.

Other Generalizations and Applications

From a more general perspective, marginal log-linear models may be seen useful, when one deals with variables, which are related in some way, and the relationship may be caused by the sampling procedure or time dependence or by other reasons, and the immediate goal is to do an analysis with reference to these relationships. Several such applications, including information about relevant software, are presented in Bergsma et al. (2009). The book also discusses the relationship between marginal log-linear modeling and structural equations modeling (SEM).

Another interesting application of marginal log-linear models is the specification and analysis of path models for categorical data. These models assume that only effects associated with the arrows present in a DAG exist among variables (Goodman, 1973). In a SEM approach, this is usually interpreted as the existence of some kind of regression equations, linking variables to their parents. Such regressions are hard to interpret in the case of categorical variables, and the path model assumption is more naturally taken as meaning that no higher order associations exists, than those including variables and one of their parents (see Rudas et al., 2006). Under such a model, the existing effects are fully quantified by the marginal log-linear parameters involving a variable and one of its parents.

Marginal log-linear models may be seen as an approach, where effects present in the joint distribution of several categorical variables, often thought of as a contingency table, include such that they involve only a group of variables (a marginal), not all. It is also possible to consider models, where effects are associated not with groups of variables, rather with arbitrary subsets of the cells of the contingency table, which have some common property. For example, Klimova and Rudas (2012) present an analysis of social mobility tables, where the effect of the distance of the son's position from the father's position is also taken into account and is quantified.

Longitudinal Analyses of Sexual Development through Early Adulthood

Joseph Gonzales and Emilio Ferrer, University of California, Davis, Davis, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Longitudinal data analysis is a category of analytic techniques used to assess data in which units (e.g., persons) are measured more than once. These techniques can be used to inform specific questions such as (1) what are the trajectories and rates of change in a behavior (e.g., latent growth modeling); (2) what are the relations of changes in behavior (e.g., bivariate latent growth models); (3) can we predict outcomes using measures of change (e.g., latent growth models with exogenous outcomes); and (4) when are events most likely to occur for individuals along some temporal metric (e.g., discrete-time survival analysis). While these questions are unique, they are all concerned with understanding patterns and relations of intraindividual change utilizing longitudinal data. In this article, we apply these methods in order to demonstrate different ways of interpreting longitudinal change in sexual behavior from late childhood through young adulthood.

Longitudinal data analysis affords researchers access to the dimension of time, that space within which developmental changes occur. While this dimension is not required to infer meaningful relations and experimental effects, it is necessary if a researcher wants to understand the dynamics of the processes in question, as it unfolds over time.

Consider, for example, the established and growing body of literature on sexual behaviors. In particular, risky sexual behaviors (e.g., Coker et al., 1994; Grello et al., 2006; Gute and Eshbaugh, 2008; Paul et al., 2000) have been linked to substance use (e.g., alcohol; Grello et al., 2006; Paul et al., 2000; Traeen and Lewin, 1992). Much of this research is based on methods utilizing single observations. Although informative in some ways, such methods limit our understanding of the intraindividual aspects of development and change. In this article, we demonstrate longitudinal modeling methods based on within-person changes (e.g., McArdle, 2009; Singer and Willet, 1993) and evaluate questions that pertain to developmental processes and their interrelations over time (Baltes and Nesselroade, 1979). To demonstrate these methods, we apply them to empirical data on sexual behavior over time to examine both behavioral change and its correlates from late childhood through early adulthood.

Behavioral Change Over Time

During the teen years, many adolescents engage in sexual behaviors for the first time (Chandra et al., 2005; Martinez et al., 2006). While these experiences seem normative and do not necessarily impair adolescents' ability to maintain various adaptive goals (e.g., educational goals and personal health), subsets of adolescents seem prone to encountering negative consequence (e.g., contraction of STDs and unplanned pregnancies) as a result of high-risk sexual behavior. One factor that has been identified as contributing to participation in high-risk sexual behaviors is alcohol use (e.g., Grello et al., 2006; Gute and Eshbaugh, 2008; Miller, 2012; Paul et al., 2000). However, the unique and interrelated development of these behaviors is generally not explicitly explored in the extant literature.

To characterize changes in sexual behavior and alcohol use, as well as their interrelations, methods based on within-person changes are needed. One such method is latent growth modeling (LGM; e.g., McArdle, 2009; McArdle and Hamagami, 2001). LGM can be used to identify changes occurring over various time metrics (e.g., age) to describe the trajectory of change (e.g., changes in the number of novel sexual partners and frequency of alcohol use; Dogan et al., 2010) and their interrelations over time. An LGM can be defined (e.g., Ferrer et al., 2004) as follows:

$$Y(t)_i = \gamma_{0i} + A(t) * \gamma_{si} + e(t)_i \qquad [1]$$

$$\gamma_{0i} = \mu_0 + e_{0i} \quad \text{and} \quad \gamma_{si} = \mu_s + e_{si} \qquad [2]$$

Where Y is an outcome measured over time ($t = 1, \ldots, T$) across the same individual ($i = 1, \ldots, I$). The coefficients γ_0 and γ_s represent the initial level and the slope of change in the outcome variable over time, respectively. The basis coefficients, $A(t)$, represent the timing or shape of growth from the slope over time, and $e(t)$ represents the unobserved error of measurement. Both the level and slope include individual differences such that they have fixed group means, μ_0 and μ_s, and residuals, e_{0i} and e_{si}.

From this initial model, several modifications can be made to explore other research questions. For example, a bivariate growth model can be built with two LGMs describing how two different growth trajectories are related to each other with respect to their starting values and their slopes (McArdle, 1988; 2009). Consider the bivariate case. This model can be written for variables $Y(t)$ and $X(t)$ over time as a model of two growth curves (e.g., Ferrer et al., 2005).

$$\begin{aligned} Y(t)_i &= \gamma_{0i} + \text{Age}_y(t)_i \cdot \gamma_{si} + e_y(t)_i \quad \text{and} \\ X(t)_i &= x_{0i} + \text{Age}_x(t)_i \cdot x_{si} + e_x(t)_i \end{aligned} \qquad [3]$$

with all covariances allowed among the latent variables ($\sigma_{y(i),\, x(i)}$). Among these covariances, $\sigma_{ys,\, xs}$ represents the covariance between the age slopes of the two variables; the degree that total change in one variable is related to total change in the other.

This bivariate model can also be written using a random coefficients, or multilevel, notation as a model with a single outcome variable Y_{itk} for individual i at occasion t on variable k, where the variables k do not need to be measured at the same occasions for all individuals as,

$$Y_{itk} = \sum_{k=1}^{m} d_k(\beta_{0ik} + \beta_{1ik} \cdot \text{Age}_{itk} + \beta_{2ik} \cdot p_{itk} + e_{itk}) \quad [4]$$

where $k = 1, \ldots, m$ represents the number of variables (two in this study), d_k is a dummy variable d_1 to d_m (1 or 0) to indicate the dependent variables, β_{0ik} is the intercept for person i on variable k, β_{1ik} is the slope associated with age for person i on variable k, and e_{itk} is the residual for person i at occasion t for variable k. Similar to the univariate case, the intercepts and slopes for the k variables can be decomposed as,

$$\begin{aligned} \beta_{0ik} &= \beta_{0k} + u_{0ik}, \quad \text{and} \\ \beta_{1ik} &= \beta_{1k} + u_{1ik}, \end{aligned} \quad [5]$$

which indicates that, for each variable k, the intercept and slope have fixed group means (β_{0k}, β_{1k}) and random residuals (u_{0k}, u_{1k}), and these residuals have variance components ($\sigma^2_{0k}, \sigma^2_{1k}$) and could covary among themselves. In addition to these within-variable k random effects, covariances between intercepts and slopes are also allowed between variables. To test specific hypotheses – or merely due to data constraints – restrictions can be imposed as needed in the covariance matrix of individual residual variances $\mathbf{T} = \text{cov}(\mathbf{E}_{nt})$ and in the between-individual covariance matrix $\Sigma = \text{cov}(U_t)$. This model can now be estimated using any standard multilevel program.

Event Occurrence or Onset

Another substantive example to consider is when are people most likely to begin engaging in sexual behavior, and what factors will delay or expedite their sexual debut. This information may be particularly helpful in timing interventions such as sex education (e.g., Somers and Surmann, 2005) by identifying periods of greater behavioral risk for various subpopulations. A longitudinal analytic approach that can be used to address this question is discrete-time survival analysis. This technique can be applied to discrete intervals of time (e.g., years) to examine the likelihood of a one-time behavioral occurrence (Singer and Willet, 1991, 1993).

Singer and Willet (1993) present a survival analysis model where survival for a given period is defined as follows,

$$s_t = s_{t-1} * (1 - h_t) \quad [6]$$

such that t represents the time period, hazard, h_t, values represent the risk of an event occurring in the (remaining) period population during a given period, and survival, s_t, represents the proportion of the surviving population during a given period.

The discrete-time hazard, h_t, is defined as the probability that a randomly selected individual, i, will have the target event occur during time period, t, given that he or she has not already experienced the event.

$$h_{it} = \frac{1}{1 + e^{-\left[\left(\alpha_1 D_{1it} + \alpha_2 D_{2it} + \cdots + \alpha_t D_{T_{it}}\right) + \left(\beta_1 Z_{1it} + \beta_2 Z_{2it} + \cdots + \beta_p Z_{Pit}\right)\right]}} \quad [7]$$

With D representing dummy coding for periods, and Z representing covariates that can be either time invariant or time variant for individuals between periods. Both invariant and variant covariates are assumed to be invariant during each time period. The intercept parameters ($\alpha_1, \ldots, \alpha_T$) describe the baseline hazard rate for each time period and the slope parameters ($\beta_1, \ldots, \beta_P$) describe the effects of the covariates on the baseline hazard rate.

Empirical Examples

In the following examples, we demonstrate how different growth models can accomplish some of the objectives of longitudinal research (Baltes and Nesselroade, 1979): (1) the identification of intraindividual change (i.e., how does the number of total sexual partners change across observation periods); (2) the analysis of interrelations in behavioral change (i.e., how do the initial levels and changes of total sexual partners and alcohol use relate to each other); and (3) how do the initial levels and changes for both total number of sexual partners and drinking behavior predict an exogenous outcome of interest (i.e., number of pregnancies). Additionally, we illustrate the application of discrete-time survival analysis with respect to a critical event in sexual development, the sexual debut. As part of this illustration, we incorporate time-invariant (i.e., biological sex) and time-variant (i.e., age of menarche) covariates to evaluate differences in risk during any given period of observation as a function of heterogeneity between individuals.

Method

Participants

We use data from the National Longitudinal Study of Adolescent Health (Add Health) (Harris and Udry, 2013). Data were collected as part of a longitudinal study of a nationally representative sample of the United States adolescents in grades 7–12 during the 1994–95 school years. The data set consists of four waves of data separated by approximately 1, 4, and 7 years (waves 1–2, 2–3, and 3–4, respectively).

A subset of participants were selected for inclusion in the present study, if their previous interview responses regarding their number of total sexual partners were less than or equal to their later responses (i.e., wave 1 $\leq$ wave 2 $\leq$ wave 3 $\leq$ wave 4). A total of 5200 participants were included in this subset, of which 47% were male and 53% were female. Ages ranged 12–21 years ($M = 16$, $\text{SD} = 1.80$) at wave 1, 13–22 years ($M = 16.5$, $\text{SD} = 1.59$) at wave 2, 18–28 years ($M = 22.22$, $\text{SD} = 1.87$) at wave 3, and 24–34 years ($M = 28.87$, $\text{SD} = 1.79$) at wave 4.

Materials and Procedure

At each wave of the study, participants responded to a battery of items both with an interviewer and independently via a computer with prompts.

Total Number of Sexual Partners

Wave 1–4 interviews utilized different methods for assessing total number of sexual partners. Wave 1 asked participants to indicate how many total sexual partners participants had; wave 2 asked for participants to indicate how many new sexual partners they had since their last interview; wave 3

asked how many total partners participants had; and wave 4 asked two questions: (1) how many total female sexual partners participants had, and (2) how many total male sexual partners participants had. Wave 2 total sexual partner counts were computed by adding wave 1 total partner counts and wave 2 new partner counts. Wave 4 total sexual partner counts were computed by summing the total male partner and total female partner values.

Participant Drinking Behavior

Wave 1–4 interviews included a question about participant drinking behavior, "During the past 12 months, on how many days have you gotten drunk?" For waves 1 and 2, participants were asked to respond using a 7-point likert scale ranging from 1 ('every day') to 7 ('never'). In waves 3 and 4, participants responded to the same question using a 7-point likert scale ranging from 0 ('never') to 6 ('every day'). Waves 1 and 2 responses were reverse coded to conform to the waves 3 and 4 reporting format.

Participant Age at Time of Interview

Participants' birth month and year were recorded as part of their participation in the study. Additionally, the month and year of each interview was also recorded. Birth month and interview month were scored 1–12 (January–December, respectively). Age at time of interview was computed by dividing birth month and interview months by 12 and adding them to birth year and interview years, respectively. This new birth year score was then subtracted from the new interview year score for waves 1–4, yielding an age at interview score for each interview wave. Two age score formats were used: (1) the computed age scores and (2) the computed age scores rounded to the nearest year.

Age of Sexual Debut

During wave 4, participants were asked at what age they first had vaginal intercourse. Reported ages ranged from 1 to 30 years old ($M = 16.82$, SD = 2.99).

Age of Menarche

Female participants were asked at wave 1–3 interviews what age, in years, they had their first menstrual period. Disagreement in age of first menstrual period was resolved by taking the average of ages reported by participants and rounding to the nearest year. Ages ranged from 7 to 17 ($M = 12.26$, SD = 1.36).

Additionally, unrounded age of first menstrual period scores for each participant were used to center participant unrounded ages to yield a participant-centered menstrual age ranging from 2.42 to 22.67 ($M = 8.36$, SD = 5.67). Negative scores indicate years prior to age of menarche, zero indicates age at menarche, and positive scores indicate years after menarche.

Number of Participant Pregnancies

During the wave 4 interview, participants were asked how many times they either became pregnant or impregnated someone else; regardless of the outcome of the pregnancy. Number of total pregnancies reported ranged from 0 to 12 ($M = 1.35$, SD = 1.55).

Results

Growth Modeling: Wave-Based Time Metric

Total Number of Sexual Partners

In the first set of analyses, we examined the trajectories of total number of sexual partners over interview waves. Figure 1 depicts the number of sexual partners across waves 1–4 and suggests that a linear growth may be an appropriate starting point. We fit no growth, linear growth, and quadratic growth models using wave as the measurement occasion. All analyses were conducted using maximum likelihood estimation. Fit for the no growth, linear growth, and quadratic growth models were poor and they were rejected as untenable models. A nonlinear LGM was estimated by constraining the wave 1 and 4 loadings from the slope to zero and one, respectively (see Figure 2), and estimating the slope's basis coefficients for waves 2 and 3.

Fit to the data with the estimated slope loadings was good (see Table 1), suggesting that this fourth model was a tenable representation of the change in number of sexual partners. Moreover, estimates of the slope loadings for waves 2 and 3 ($\alpha = 0.07$ and 0.36, respectively) conform to expectations from the graphs of the data: there is little growth from wave 1 to 2, and transitions from wave 2 to 3, and wave 3 to 4 represent the majority of change in total number of sexual partners.

While this rate of change may not seem linear, it should be noted that time from wave 1 to 2 is about 1 year. In contrast, from wave 2 to 3 is about 4 years, and from wave 3 to 4 is about 7 years. Thus, the average yearly rate of change from wave 2 to 3 was about 0.09, and the average yearly rate of change from wave 3 to 4 was also about 0.09. While we cannot use waves to evaluate if this rate of change was constant between unobserved years, it does suggest that growth may have been relatively constant across the overall period of observation.

Ratings of Days Drunk

The same no growth, linear growth, and quadratic growth models were next fit to participants' drinking behavior ratings. Again, fit for each model was poor and they were rejected. As with total number of sex partners, a nonlinear LGM was fit to the data constraining the wave 1 and 4 loadings from the slope to zero and one, respectively.

Fit to the data was good (see Table 1), suggesting that this fourth model was a tenable representation of the change in ratings of drinking behavior. Again, the estimates of slope loadings for waves 2 and 3 ($\alpha = 0.19$ and 1.08, respectively) conform well to expectations based on plots of the data (see Figure 1), such that there was a peak in drinking behavior at wave 3, with a slight decline at wave 4.

As with total number of sexual partners, it is worth noting that these rates of change are not for equivalent periods of time if considered with respect to the number of years that pass between waves of data collection. Here, the average yearly rate of change from wave 2 to 3 is about 0.22, and the yearly rate of change from wave 3 to 4 is about 0.01. This suggests that the average yearly rate of change from wave 1 to 3 may be very similar, and that there was very little yearly change from wave 3 to 4.

Figure 1 Changes in the total number of sexual partners and drinking behavior over waves of participant interviews. The graph on the top-left depicts the individual increase in total number of sexual partners for 50 randomly selected participants. The graph on the top-right depicts the average change in total number of sexual partners using the solid black line, with 1 SD errors around the mean value indicated by dashed lines. The graph on the bottom-left depicts individual drinking behavior trajectories of 50 randomly selected participants. The graph on the bottom-right depicts the average change in drinking behavior using a solid black line, with 1 SD errors around the mean value indicated by dashed lines. Note that the error bars have no values below zero as a score less than zero is not possible. Also note that variability in total number of sexual partners is very large in wave 4 relative to waves 1–3, and that variability for this measure is lowest in wave 1 relative to waves 2–4.

Bivariate Model for Number of Sex Partners and Drinking

Having developed tenable growth models for total number of sex partners and drinking behavior across waves, we next fit a bivariate growth model to examine the relation between these two processes with respect to their initial levels and changes over time. For this, we specified a model in which the intercepts and slopes of both variables were allowed to covary (see Figure 3). These covariances describe relations between latent growth factors for total number of sexual partners and drinking behavior.

Figure 2 Path diagram of a growth model with four points of observation for a single manifest variable. Lines with double-arrows represent covariances and variances. Lines with single arrows represent regressions or factor loadings. Y_0 represents the level and Y_S represents the slope.

Model fit to the data was excellent (see Table 2). To ease interpretation, covariances were standardized into correlations. Parameter estimates of bivariate relations between both variables indicate a positive correlation between the initial ratings of drinking behavior and number of sexual partners ($r = 0.38$, $p < 0.01$), but no relation between total change in number of sexual partners and change in drinking behavior ($r = 0.04$, $p = 0.12$). These results indicate that drinking behavior and total number of sexual partners are related initially, but that their changes are not.

Bivariate Growth with an Exogenous Outcome

Next, we added an exogenous outcome that is regressed upon the levels and slopes for total number of sexual partners and drinking behavior. Given interest in the possible relation between number of pregnancies and number of sexual partners, a substantively interesting outcome is the total number of pregnancies reported by the participants. Again, model fit was excellent, and estimates varied very little with the previous bivariate model (see Table 2).

Estimates indicate that both the level and slope of drinking behavior are negatively related to number of pregnancies,

Note: Y_0 denotes the latent level for each growth model and *Ys* denotes the latent slope for each growth model. Tsex1–4 indicates manifest scores of total number of sexual partners at waves 1–4, respectively. Drink 1–4 indicates manifest scores of self-reported ratings of days the participant was drunk over the last 12 months at waves 1–4, respectively. Cor indicates the correlation between the level and slope for each growth model. Level loadings for waves 1–4 were constrained to equal one in both models, and wave 1 and 4 slope loadings were constrained to equal 0 and 1, respectively, in both models. CFI and RMSEA are measures of model fit. RMSEA consists of its score followed by its 90% CI in parentheses.

Figure 3 Path diagram of bivariate latent growth model. Lines with double-arrows represent covariances and variances. Lines with single arrows represent regressions or factor loadings. Note the covariances between the levels and slopes for total number of sex partners (S_0 and S_S) and drinking behavior (D_0 and D_S). For convenience, residuals were not depicted in the model.

whereas level and slope of number of sexual partners are positively related to number of pregnancies. Differences in the reported (unstandardized) estimates may lead one to suspect that latent growth factors for ratings of drinking behavior are stronger predictors of number of pregnancies. However, such differences are partially a result of variable metrics. The standardized coefficients for level and slope of number of sexual partners ($\beta = 0.08$ and 0.19, respectively) and drinking behavior

Note: In both models the levels and slopes of total number of sexual partners and days drunk ratings were allowed to covary. Y_0 denotes the intercept and Y_1 denotes the slope. Tsex is total number of sex partners, Alc is ratings of days drunk, and Npreg is the total number of pregnancies participants reported having or caused during the wave 4 interview. Number of pregnancies was regressed on the total number of sexual partners and days drunk rating levels and slopes in the 'With Pregnancy Outcome' model. CFI and RMSEA are measures of model fit. RMSEA consists of its score followed by its 90% CI in parentheses.

($\beta = -0.19$ and -0.38, respectively) show that these differences in magnitude are not as pronounced as they initially appeared.

Growth Modeling: Age-Based Time Metric

One limitation of the previous models is that while they evaluate the temporal interrelations of two variables of interest, they do so using a time metric of little substantive value. Saying that the number of total sex partners changed from wave 1 to wave 2 means little to a substantive researcher who may be interested in how these changes occur over a given period of time (e.g., adolescence). Yet, many longitudinal studies produce panel data much like this, consisting of a cross-sectional sampling of participants at different ages over a period of time.

A more meaningful approach, especially from a developmental perspective, would be to model change in total number of sex partners and drinking behavior using age as the underlying metric (see Figure 4). To illustrate this possibility, we fit the individual and bivariate models using age as the time metric. Additionally, rather than using discrete-time intervals, we now treat the time interval as continuous with all age scores centered using the lowest observed age in the sample, 1 158 333 years.

Unlike the wave-based models using discrete time, there are no longer individual slope loadings estimated for time intervals (see Table 3). Similar to the wave-based models, we still estimate an initial level for both total number of sexual partners and drinking behavior ($\gamma_o = -3.11$ and 0.45, respectively), which now represents the expected values of the outcome variable when age is 1 158 333 years. Additionally, we estimate a slope for number of sexual partners and drinking behavior ($\gamma_s = 0.9$ and 0.04, respectively), which now represents the expected amount of change in the outcome for each year of age.

Also like the wave-based models, we can model both outcomes at the same time and investigate the relation between the total number of sexual partners and drinking behavior with respect to their levels and slopes. These relations differ from the previous model in several interesting ways. First, the levels of number of sexual partners and drinking behavior are no longer related ($r = -0.1$, $p = 0.06$). This could be because at the initial age in this sample there is not much occurrence of either behavior. In contrast, the wave-based format includes participants in wave 1 who were an average of 4 years older than the continuous age intercept, with higher corresponding scores and variability of both total sex partners and drinking behavior. Second, the association between the changes in total number of sexual partners and those of drinking behavior is now positively related ($r = 0.22$, $p < 0.01$), suggesting that changes in both behaviors are related.

It is evident that by using a different time metric, we find differences that suggest distinct relations between total number of sex partners and drinking behavior. Specifically, when examined across waves the initial levels of both variables are related but their changes are not. When evaluated over age, this is reversed and the changes are correlated but the initial levels are not. In spite of these otherwise unsurprising discrepancies, when we regressed the exogenous variable, total

Figure 4 Change in total number of sex partners and ratings of days spent drunk across participant age. This demonstrates an alternative and developmentally meaningful time metric across which to plot changes in total number of sexual partners and ratings of days spent drunk.

number of pregnancies, on our levels and slopes for total number of sexual partners and drinking behavior we find that results are fairly similar.

Growth Modeling: Menstrual Age-Based Time Metric

To further emphasize the possibility of using different time metrics when modeling longitudinal data, we now consider a model of female participants based upon menstrual age (see Figure 5). We centered female participants' age by their age of menarche. This yields a menstrual age score for each participant where negative age scores indicate premenarche age, zero represents age of menarche, and positive scores indicate postmenarche age. While each female participant may have experienced menarche at a different age, in this format they are centered to be on the same menstrual-age metric.

Again, we modeled the menstrual age continuously, and therefore do not have individual slope loadings for individual ages (see Table 4). However, as with the previous age model,

Table 3 Growth models using continuous age in years as time metric

Note: In the bivariate models, the levels and slopes of total number of sexual partners and days drunk ratings were allowed to covary. Y_0 denotes the intercept and Y_1 denotes the slope. Tsex is total number of sex partners, Alc is ratings of days drunk, and Npreg is the total number of pregnancies participants reported having or caused during the wave 4 interview. Number of pregnancies was regressed on the total number of sexual partners and days drunk rating levels and slopes in the 'Bivariate Model with Covariate' subtable.

Figure 5 Change in female total sex partners and ratings of days drunk across participant menstrual age. This demonstrates an alternative and developmentally meaningful time metric across which to plot changes in total number of sexual partners and ratings of days spent drunk.

we still estimate an initial level and a slope for both total number of sex partners and drinking behavior, and these estimates can be evaluated for interrelations and predictive ability of exogenous variables.

While estimates may differ from previous models due to the use of an alternative time metric, variations could also be a result of heterogeneity between male and female participants (i.e., average female and male trajectories may differ). In this case, relations between the slopes and levels of total sex partners and drinking behavior were quite similar to the previous age-based model. Differences included a positive relation between the levels for total sex partners and drinking behavior ($r = 0.13$, $p < 0.01$), and a non-significant relation between the level of drinking behavior and the slope of total sex partners ($r = 0.06$, $p = 0.11$). This suggests that females have a positive relation between drinking behavior and number of sexual partners at their age of menarche, but not between their age of menarche drinking behavior and rate of change in total sex partners. Finally, evaluation of our bivariate model with our exogenous

	Alc Y_1	–	–	–		Alc Y_1	−10.1	1.56	<0.01

Note: In the bivariate models, the levels and slopes of total number of sexual partners and days drunk ratings were allowed to covary. Y_0 denotes the intercept and Y_1 denotes the slope. Tsex is total number of sex partners, Alc is ratings of days drunk, and Npreg is the total number of pregnancies participants reported having or caused during the wave 4 interview. Number of pregnancies was regressed on the total number of sexual partners and days drunk rating levels and slopes in the 'Bivariate Model with Covariate' subtable.

outcome, number of pregnancies, regressed on slopes and levels yielded near identical estimates as with our previous model using continuous age. This suggests very little change in prediction of the exogenous outcome as a result of the change in time metric or focus on a subpopulation of female participants.

Discrete-Time Survival Analysis

Data Preparation

Survival analysis required the creation of a person-period data set (Singer and Willet, 1991, 1993). This data set contains a series of individual observations indicating sexual debut status, biological sex, and menarche status. The target event is coded as zero for time periods during which sexual debut did not occur, and one for the time period in which it did occur for each person. The records are censored such that after sexual debut occurs for a person, no further observations for that person are included in the data set. Finally, due to the repeated observations across periods, covariates are capable of being modeled as invariant or variant. For all participants, biological sex was coded as invariant for each observation. In contrast, female participants' menarche status was variant, and indicated if female participants' observations were pre- or postmenarche onset.

Male and Female Sexual Debut

First, a baseline survival model of male and female participants' sexual debut was created using year of observation. Figure 6 shows the survival and hazard rates for sexual debut from 12 to 25 years of age. The survival portion of the figure shows the proportional decline of the remaining population who have not had their sexual debut for each year relative to the starting population of participants. The hazard portion of the figure shows the proportion of surviving participants having their sexual debut during each year.

Results indicated that risk of sexual debut began increasing with the onset of adolescence. By 15 years of age, hazard rates increased to 18% with 23% of participants having reported having their sexual debut. By 16 years of age 51% of participants reported having their sexual debut, and by 18 years of age 78% of participants had their sexual debut. Note that estimates for 25 years of age were not significant (see Table 5). This may be due to data sparseness at the more extreme age of target behavior occurrence. As is expected, this suggests that estimates may be less robust where there are fewer data points.

A second model of sexual debut was developed as an extension of the previous model with the addition of a time-invariant covariate – biological sex. The variable was dummy coded with male as the reference (coded as zero), and female as the change in value (coded as one). The parameter estimate for the 'Female' covariate was not significant (see Table 5). Figure 7 depicts this difference in survival and hazard rates where the solid line with circles indicates the projected rates for participants who are male and the dashed line with pluses indicates the projected rates for participants who are female. Note the almost perfect overlap between lines indicating the lack of a biological sex effect. These models were compared for improvement in fit using change in -2 log likelihood evaluated with a chi square distribution. Given the lack of effect of biological sex, the significance of improved fit between models was unexpected ($\Delta\chi^2 = 7.8$, $\Delta df = 1$, $p < 0.01$).

Female Sexual Debut and Menarche

A third survival analysis model was fit exclusively to data from females. As with the male and female survival analyses, a baseline survival model was fit to the data (see Table 6). As expected given the previous comparison between males and females, the female-only baseline model was essentially identical to the previous models. This time we expanded on the baseline model by including a time-varying covariate – participants' menarche status. Menarche status is time-varying,

Figure 6 Virginity survival and hazard rates for participants from 12 to 25 years of age. Rate of decline in survival accelerated as participants entered the teen years with 23% of participants having engaged in first-time vaginal intercourse by the age of 15. It is also at age 15 that the hazard rate rises above 20%, which it will not drop below for the remainder of observations. The peak surges in hazard are at ages 18, 21, and 25.

y_{18}	−0.50	0.06	<0.01	−0.53	0.06	<0.01
y_{19}	−0.88	0.08	<0.01	−0.90	0.08	<0.01
y_{20}	−0.98	0.09	<0.01	−1.02	0.10	<0.01
y_{21}	−0.54	0.10	<0.01	−0.56	0.10	<0.01
y_{22}	−0.70	0.13	<0.01	−0.73	0.13	<0.01
y_{23}	−0.90	0.17	<0.01	−0.92	0.17	<0.01
y_{24}	−0.68	0.19	<0.01	−0.71	0.19	<0.01
y_{25}	−0.22	0.22	0.32	−0.25	0.22	0.26
Female	–	–	–	0.05	0.04	0.22

Note: −2LL (2 Log Likelihood) for the 'No Covariate' model was 17 458.59, and −2LL for the 'Time-Invariant Covariate' model was 17 450.74. Their difference is 7.84 with 1 d*f*, which is a significant change in fit ($p < 0.01$). Parameters y_{12}–y_{25} are the dummy coded period variables. The nonsignificant estimate for 25 years of age may be a consequence of sparse data, suggesting that greatest confidence be placed in describing hazard and survival rates in late childhood through early adulthood.

as participants may begin observations having not experienced menarche (coded as zero) and may change to having experienced menarche (coded as one) prior to the occurrence of the target event and data censorship.

Results indicate that having experienced menarche significantly predicts occurrence of sexual debut. Female participants are 1.57 times more likely to have their sexual debut during a time period once they have experienced menarche compared to time periods prior to menarche. Figure 8 depicts this difference in survival and hazard rates. The solid line with circles indicates the projected rates for participants who have not experienced menarche and the dashed line with pluses indicates the projected rates for participants who have experienced menarche.

Comparisons of model fit show that the second model including the menarche status covariate fit the data significantly better than the baseline model ($\Delta\chi^2 = 23.82$, $\Delta df = 1$, $p < 0.001$).

Discussion

Summary of Findings

In this article, we used LGM to describe changes in the number of sexual partners, drinking behavior, their interrelations, and their power to predict number of pregnancies. Using measurement occasion as the time metric in our analyses, we concluded that neither number of sexual partners nor drinking behavior could best be described as changing linearly or quadratically over time. Rather, we found that increases in total number of sexual partners was greatest from waves 2 to 3 and 3 to 4, and that drinking behavior peaked in wave 3 and then declined slightly in wave 4. We also found that change in drinking behavior and number of sexual partners was not significantly related, but that their levels and slopes were. This suggests that there is an initial relation and effect on rate of change, but that overall change is not related. Finally, we determined that drinking behavior seems to be prohibitive to individuals' total number of pregnancies, but that number of sexual partners is a positive predictor of total number of pregnancies. It is not clear if the prohibitive effect of drinking has to do with decreasing the number of planned pregnancies with committed partners, nor is it clear if the positive relation between the number of sexual partners and pregnancies is indicative of pregnancies during uncommitted or committed relationships that were planned or unplanned.

In a second set of analyses we used more substantive time metrics (i.e., participants' age and female participants' menstrual age). We found that with the recoding of the time metric interrelations between the level and slope of total

Figure 7 Comparison of male and female virginity survival and hazard rates for participants from 12 to 25 years of age. There was no significant difference in model fit with the inclusion of the 'Female' covariate. As a result, there is virtually perfect overlap between male and female survival and hazard rates.

Note: −2LL (2 Log Likelihood) for the 'No Covariate' model was 9763.84, and −2LL for the 'Time-Varying Covariate' model was 9740.02. Their difference is 23.82 with 1 d*f*, which is a significant change in fit ($p < 0.01$). Parameters y_{12}–y_{25} are the dummy coded period variables. The nonsignificant estimate for 25 years of age may be a consequence of sparse data, suggesting that greatest confidence be placed in describing hazard and survival rates in late childhood through early adulthood.

number of sex partners and drinking behavior differed. Using the wave-based metric the correlation between the two slopes was not significant, but this relation was significant when using both the age-based and menstrual age-based metrics. Additionally, there was some disagreement between the age-based and menstrual age-based models with respect to the relation between the two levels ($r = -0.10$ and 0.13, respectively). But it is not clear if this is a result of change in time metric, heterogeneity between males and females, or both.

Finally, we used discrete-time series analysis to examine the likelihood of sexual debut during adolescence and early adulthood. Our findings indicated that the risk of sexual debut begins to increase in early adolescence for both males and females. By the age of 15, 23% of the participants in our sample had their sexual debut. By 16, that proportion more than doubled to 51%. We also found that there was no significant difference in hazard and survival rates between males and females in our sample, but model fit improved significantly when the covariate was included.

However, when applying the same model to females only, we found that having experienced menarche increased the odds of having their sexual debut by 1.57 times. While it is not clear what may be driving this effect, it is likely that the onset of ovulation has a direct effect on females' own interest in, and attraction to, romantic partners and sexual activity. Additionally, it is possible that postmenarche females are physically more developed than their premenarche peers, making them more desirable partners to males.

Substantive Implications

An overarching implication of our results is that the conclusions one can reach about the relation between drinking behavior and number of sexual partners will vary depending on how the question is asked, and consequently analyzed. While there are scenarios in which the wave metric can be of interest (e.g., evaluating practice effects), in our illustration such effects are unlikely and evaluations of changes over age and menstrual age are more meaningful to understanding developmental change. Estimates from the continuous age model suggest that there is a positive relation between changes in drinking behavior and number of sexual partners over this period.

These models do not allow inferences about relations between these behaviors beyond the observed range of ages. However, over the developmental period studied, we observed that participants who had greater changes in drinking behavior had corresponding changes in their number of sexual partners. Similarly, while this relation is often expected given single-observation research, this model suggests that this is a relation that may exist within individuals over time, such

Figure 8 Comparing female virginity survival and hazard rates based on age of menarche. There was a significant difference in model fit with the inclusion of the 'age of menarche' covariate. Females were 1.57 times as likely to engage in first-time vaginal intercourse if they had experienced menarche compared to their peers who had not. This difference emerges in late childhood and early adolescence, becomes pronounced around ages 15–16, and is maintained through the remaining observation periods.

that changes in drinking behavior over time are related to the total number of sexual partners over time as well.

Our survival analysis indicates that there was relatively little difference between male and female participants with respect to risk of sexual debut. This suggests that the optimum timing for sexual education may not differ between male and female adolescents. Additionally, depending on the education strategy to be employed, these data may also indicate periods for optimum repetition of education with respect to increasing risk of sexual debut.

Methodological Limitations

The sexual debut data do not represent yearly observations. Rather, it was derived from a single observation for each participant. This may be problematic given potential inaccuracy due to retroactive reporting. For example, participants may retroactively alter the age of their sexual debut, or recall the timing differently than they would have around the time of the actual event.

Generally, this approach has two limitations with respect to the length of the time periods and estimation of covariate effects. Regarding the former, we were able to use time in years because that was the precision of time intervals inherent in the event record. However, this may not be the best time metric to describe occurrence of sexual debut. As for the latter, the effect of covariates is implicitly modeled as constant across time periods. However, this assumption may not be reasonable. For example, postmenarche status likely impacts 16-year-old females differently than 21-year-old females.

Conclusions

Overall, this article is meant to serve as an example of how longitudinal data can be analyzed using discrete and continuous time analyses aimed at answering questions about intra-individual change over time. Specifically, our objective was to demonstrate how developmental processes can be differently described and understood via a series of similar analytic techniques, such that small variations in modeling can address a breadth of substantive research questions. While these examples are by no means exhaustive, they demonstrate well how the same modeling framework can be used to approach questions about longitudinal data in several substantively different ways.

Longitudinal Causal Inference

Miguel A Hernán and James M Robins, Harvard School of Public Health, Boston, MA, USA

Abstract

This article introduces fundamental concepts for making inferences about treatments with values that may change over time. We define time-varying treatments and confounders, and provide a classification of treatment strategies. We also describe key identifiability conditions, and the bias of traditional adjustment methods when the time-varying confounders are affected by previous treatment.

Time-Varying Treatments

Many causal questions involve treatments that vary over time (*see* Longitudinal Data). For example, we may be interested in estimating the causal effects of medical treatments, lifestyle habits, employment status, marital status, occupational exposures, etc. Because these treatments may take different values for a single individual over time, we refer to them as time-varying treatments. Robins (1986, 1987, 1997) proposed a general counterfactual model that permits the estimation of total and direct effects of fixed *and* time-varying treatments in longitudinal studies, whether randomized or observational (*see* Observational Studies: Overview).

Unlike causal contrasts for fixed treatments, causal contrasts that involve time-varying treatments need to incorporate time explicitly. To see this, first consider a fixed (non-time-varying) dichotomous treatment A that takes value 1 if an individual i receives treatment and 0 otherwise. (We assume subjects are independent and identically distributed and thus suppress the i subscript in A_i) The average causal effect of A on the outcome Y is defined as the contrast between the mean counterfactual outcome $Y^{a=1}$ under treatment and the mean counterfactual outcome $Y^{a=0}$ under no treatment, e.g., $\mathrm{E}(Y^{a=1}) - \mathrm{E}(Y^{a=0})$ (*see* Causal Inference: Overview). That is, questions about the average causal effect are questions about whether the mean under treatment differs from the mean under no treatment.

Now consider a time-varying dichotomous treatment A_k that takes value 1 if an individual receives treatment at time k and 0 otherwise. We use an overbar to denote treatment history, that is, $\overline{A}_k = (A_0, A_1, \ldots A_k)$ is the history of treatment through time k, where k can take values 0, 1, 2…K. When we refer to the entire treatment history through K, we often represent $\overline{A}_K$ as $\overline{A}$ (without a time subscript). The average causal effect of the time-varying treatment $\overline{A}$ on the outcome is not uniquely defined because there are many possible contrasts of interest that depend on the values of each of the components of $\overline{A}$. In particular, the average causal effect of $\overline{A}$ cannot be defined as a contrast between the mean counterfactual outcome under treatment and the mean counterfactual outcome under no treatment, because such contrast does not specify the time of treatment. Do we mean treatment at time 0? At time 3? At all times between 0 and K?

As an example, consider an observational 5-year follow-up study of individuals infected with the human immunodeficiency virus (HIV) who have never received antiretroviral therapy A_k before the start of the study at time 0, i.e., $A_{-1} = 0$ for all individuals. The time subscript k for treatment A_k can take 60 values: 0, 1, 2…59 months. An individual who receives treatment continuously throughout the follow-up has treatment history $\overline{A} = (A_0 = 1, A_1 = 1, \ldots A_{59} = 1) = (1, 1, \ldots 1)$, or $\overline{A} = \overline{1}$. Analogously, an individual who never receives treatment during the follow-up has treatment history $\overline{A} = (0, 0, \ldots 0) = \overline{0}$. Most individuals are treated only during part of the follow-up, and therefore have intermediate treatment histories with some 1s and some 0s – which we cannot represent as compactly as $\overline{1}$ and $\overline{0}$. For simplicity, let us assume that no individuals are lost to follow-up or die during this period, and that all variables are perfectly measured.

Now let $Y_{K+1} = Y_{60}$ be the concentration of HIV in the blood – the viral load – at the end of follow-up. For simplicity of notation we will refer to Y_{K+1} as Y. We would like to know whether treatment $\overline{A}$ affects the mean of Y. But we can no longer define the average causal effect of a time-varying treatment as a contrast of the sort $\mathrm{E}(Y^{a_k=1}) - \mathrm{E}(Y^{a_k=0})$, because such contrast only involves treatment at a single time k. Rather, we will have to define the average causal effect as a contrast between the counterfactual mean outcomes under two treatment strategies that involve treatment at all times between the start ($k = 0$) and the end ($K = 60$) of the follow-up.

Treatment Strategies

A treatment strategy – also referred to as a treatment plan or a treatment regime – is a rule that assigns treatment to each individual at each time k. In our HIV example, two treatment strategies are 'always treat' and 'never treat' during the follow-up. The strategy 'always treat' is represented by $\overline{a} = (1, 1, \ldots 1) = \overline{1}$, and the strategy 'never treat' is represented by $\overline{a} = (0, 0, \ldots 0) = \overline{0}$. Following conventional statistical terminology, we use lowercase letters to denote possible realizations of a random variable, e.g., a_k is a possible realization of treatment A_k.

We can now define an average causal effect of $\overline{A}$ on the outcome $Y_{K+1} = Y$ as the contrast between the mean counterfactual outcome $Y^{\overline{a}=\overline{1}}$ under the strategy 'always treat' and the mean counterfactual outcome $Y^{\overline{a}=\overline{0}}$ under the strategy 'never treat,' e.g., $\mathrm{E}(Y^{\overline{a}=\overline{1}}) - \mathrm{E}(Y^{\overline{a}=\overline{0}})$. There are many other possible causal effects for the time-varying treatment $\overline{A}$, each of them defined by a contrast of outcomes under two particular treatment strategies. For example, we might be

interested in the average causal effect defined by the contrast $E(Y^{\bar{a}}) - E(Y^{\bar{a}'})$ that compares the strategy 'treat at every other month' = (1, 0, 1, 0…) with the strategy 'treat at all months except the first one' $\bar{a}' = (0, 1, 1, 1\ldots)$. There are 2^K possible combinations of values rule $(a_0, a_1, \ldots a_K)$ for dichotomous a_k, and therefore 2^K such treatment strategies. However as we next explain these 2^K such strategies do not exhaust all possible treatment strategies.

In our HIV example, the time-varying covariate CD4 cell count, L_k, is measured (in cells per μl) each month k in all individuals. A low CD4 cell count is an indicator of bad prognosis among HIV-infected individuals. We could then consider the strategy "do not treat before CD4 cell count drops below 500, always treat after CD4 drops below 500, regardless of future CD4 cell counts." This treatment strategy is different from the ones considered in the previous paragraph because we cannot represent it by a rule $\bar{a} = (a_0, a_1, \ldots a_K)$ under which all individuals get treatment a_0 at time $k = 0$, a_1 at time $k = 1$, etc. Now, at each time, some individuals will be treated and others will be untreated. This is an example of a *dynamic treatment strategy*, a rule in which the treatment a_k at time k depends on the evolution of an individual's history of time-dependent covariate(s) $\bar{L}_k$ and possibly on treatment $\bar{A}_{k-1}$. Strategies $\bar{a}$ for which treatment does not depend on the evolution of time-dependent covariates we refer to as nondynamic or *static treatment strategies*.

Formally, a dynamic strategy is a rule $g = [g_0(\bar{a}_{-1}, \bar{l}_0), g_1(\bar{a}_0, \bar{l}_1), \ldots g_K(\bar{a}_{K-1}, \bar{l}_K)]$, where $g_k(\bar{a}_{k-1}, \bar{l}_k)$ is a function that specifies the treatment assigned at k to an individual with past history $(\bar{a}_{k-1}, \bar{l}_k)$. In our HIV example, $g_k(\bar{a}_{k-1}, \bar{l}_k)$ is 1 if an individual's $\bar{l}_k$ implies that his CD4 cell count dropped below 500 at or before k; otherwise $g_k(\bar{a}_{k-1}, \bar{l}_k)$ is 0. To make the notation uniform, we will also refer to static strategies as g, with the understanding that the functions $g_k(\bar{a}_{k-1}, \bar{l}_k)$ for static strategies do not depend on the covariate history $\bar{l}_k$.

All of the strategies described above are *deterministic treatment strategies* because they assign a particular value of treatment (0 or 1) to each individual at each time. More generally, we could consider *random treatment strategies* that do not assign a particular value of treatment, but rather a probability of receiving a treatment value. Random treatment strategies can be static (e.g., "independently at each month, treat a subject with probability 0.3 and do treat with probability 0.7") or dynamic (e.g., "independently at each month treat subjects whose CD4 is currently below 500 with probability 0.3, but do not treat subjects with current CD4 count exceeding 500"). See Young et al., (2014) for a taxonomy of treatment strategies.

In summary, causal inference with time-varying treatments involves the contrast of counterfactual outcomes under two or more treatment strategies. The average causal effect of a time-varying treatment is not defined unless we define the strategies that are being compared. In our HIV example, the difference $E(Y^g) - E(Y^{g'})$ measures the average causal effect of strategy g (say, 'always treat') versus strategy g' (say, 'never treat'), whereas the difference $E(Y^g) - E(Y^{g''})$ measures the average causal effect of strategy g ('always treat') versus strategy g'' (say, "treat after CD4 drops below 500"). There is not a single definition of average causal effect for time-varying treatments.

Time-Varying Confounders

Consider again our follow-up study of the effect of antiretroviral therapy $\bar{A}$ on viral load Y at the end of follow-up in HIV-infected subjects. The time-varying covariate CD4 cell count, L_k, is a proxy for the true, but unmeasured and unknown, immunosuppression level U. The greater a subject's *unmeasured* immunosuppression level U, the greater her viral load Y and the lower the CD4 cell count L_k. Every month k, a treatment decision A_k is made based on the value of CD4 cell count L_k. The lower the CD4 cell count, the more likely a patient is to be treated. Note that both the variable U and the outcome Y could be time varying too, but that is irrelevant to our current discussion. (Time-varying indicators of failure would be needed to represent a survival analysis setting (*see* Survival Analysis: Introduction) in which the outcome is, say, death.)

The causal diagram (Spirtes et al., 1993; Pearl, 1995) in Figure 1 depicts the first two time points of our study. To avoid clutter, let us assume that, in truth but unknown to the investigators, treatment has no causal effect on the outcome of any individual, i.e., the sharp null hypothesis holds and hence there are no causal paths from any of the treatment nodes A_k to the outcome Y. Also to avoid clutter, we have omitted the node L_0 for baseline CD4 cell count. (Baseline treatment A_0, and perhaps subsequent treatment, would generally be decided after observing L_0, but the inclusion of L_0 in the causal diagram would not add any conceptual insights to the discussion in this article.)

Under the structure depicted in Figure 1, we say that there is confounding for the effect of the treatment A_1 on the outcome Y because A_1 and Y share the cause U, i.e., because there is a backdoor path between A_1 and Y through U. This backdoor path $A_1 \leftarrow L_1 \leftarrow U \rightarrow Y$ cannot be blocked by conditioning on the common cause U because U is unmeasured and therefore unavailable to the investigators. However, this backdoor path can be blocked by conditioning on L_1, which is measured. Note that a second backdoor path gets open after conditioning on L_1. This second backdoor path $A_1 \leftarrow A_0 \rightarrow L_1 \leftarrow U \rightarrow Y$ can be blocked by conditioning on prior treatment A_0, which should be available to investigators. Thus, if the investigators collected data on L_1 for all individuals, there would be no unmeasured confounding for the effect of A_1 given L_1 and A_0. We say that L_1 is a confounder for the effect of A_1 because it is needed to eliminate confounding, even though the actual common cause of A_1 *and* Y was the unmeasured U.

Now imagine the very long causal diagram that contains all time points k. At each time k, the covariate history $\bar{L}_k$ will be needed, together with the treatment history $\bar{A}_{k-1}$, to block the backdoor paths between the treatment A_k (and perhaps future treatment A_t, for $t > k$) and the outcome Y. We say that

Figure 1 Causal diagram of a study with time-varying treatment A_k and confounders L_k, and with treatment–confounder feedback. For simplicity, only the first two time points are shown.

the time-varying covariates in $\overline{L}_k$ are *time-varying confounders* for the effect of the treatment strategy g on Y because $\overline{L}_k$ includes postbaseline covariates that are needed to eliminate confounding at several, or all, times k in the study. To validly estimate the effect of a treatment strategy g without bias, we need to be able to validly estimate the joint effect of all A_k simultaneously and without bias (Robins, 1986). It can be shown that, for static regimes, blocking the backdoor path for every component k of the time-varying treatment A_k is a sufficient (but not necessary) condition for valid estimation of the causal effect of treatment strategies g that involve the time-varying treatment A_k (Pearl and Robins, 1995).

Suppose treatment A increases future CD4 cell count, and the presence of low CD4 count increases the probability of receiving treatment. That is, in our example there is a feedback loop between treatment and confounders. Interestingly, a causal diagram like the one in **Figure 1** – an acyclic graph – can be used to represent the treatment–confounder feedback loop – a cycle – by elaborating the feedback loop in time. This approach to visually representing feedback cycles with acyclic graphs requires that time be represented as a discrete variable. That is, the causal diagram implies that treatment and covariates only change at each prespecified time k from 0 to K. This forced discretization of time is not a limitation in practice: the length of the intervals k can be chosen to be as short as the granularity of the data requires. For example, in a study where individuals see their doctors once per month or less frequently (as in our HIV example), time may be safely discretized into month intervals. In other cases, year intervals or day intervals may be more appropriate.

The treatment–confounder feedback, however, is not a necessary feature of time-dependent confounders. That is, the time-varying covariates $\overline{L}_k$ would be time-varying confounders even if they were not affected by prior treatment. We chose to present a causal diagram with treatment–confounder feedback because that setting creates an interesting problem for causal inference: when the time-varying confounders $\overline{L}_k$ are affected by prior treatment, confounding adjustment cannot be handled by conventional methods to adjust for confounding (Robins, 1986). Rather, g-methods are needed to appropriately adjust for time-varying confounders affected by prior treatment. We explore this problem below. First, we describe the identifiability conditions for the effects of time-varying treatments.

Sequential Exchangeability and Identifiability Conditions

Making causal inferences about fixed treatments requires measuring and adjusting for a set of covariates L – informally, the confounders – required to achieve conditional exchangeability $Y^a \perp\!\!\!\perp A|L$. This condition holds in conditionally randomized experiments in which individuals are assigned treatment with a probability that depends only on the values of their covariates L. The condition also holds in observational studies in which the probability of receiving treatment depends on the measured covariates L and, conditional on L, does not depend on any unmeasured, independent predictors U of the outcome. When exchangeability $Y^a \perp\!\!\!\perp A|L$ holds, we can obtain consistent estimates of the average causal effect of treatment via any methods that appropriately adjust for the variables in L, such as standardization and inverse probability (IP) weighting.

Similarly, making causal inferences about treatment strategies requires measuring and adjusting for the time-varying covariates $\overline{L}_k$ – the time-varying confounders – required to achieve a sequential version of conditional exchangeability that encompasses all time points in the study. This condition holds in (ideal) sequentially randomized experiments in which individuals are assigned treatment at each time k with a probability that depends only on the values of their prior covariate history $\overline{L}_k$ and treatment history $\overline{A}_{k-1}$. The condition also holds in observational studies in which the probability of receiving treatment at each time depends on their treatment and covariate history $(\overline{A}_{k-1}, \overline{L}_k)$ and, conditional on this history, does not depend on any unmeasured predictors U of the outcome.

In the HIV example summarized in **Figure 1**, this sequential exchangeability holds because there are no arrows into treatment A_1 from any unmeasured cause U of the outcome: all arrows into treatment A_1 come from prior treatment A_0 and covariates L_1. That is, **Figure 1** represents a sequentially randomized trial in which treatment A_0 is marginally randomized and treatment A_1 is conditionally randomized given A_0 and L_1. The treated and the untreated at time 1 are exchangeable conditional on A_0 and L_1. Sequential exchangeability – the combination of $Y^g \perp\!\!\!\perp A_0$ and $Y^g \perp\!\!\!\perp A_1|L_1, A_0$ – holds for all treatment strategies g that involve the time-varying treatment (A_0, A_1).

Now imagine the very long causal diagram with many time points $k = 0, 1 \ldots K$ that represents a sequentially randomized trial in which treatment A_k at each time k is randomly assigned conditional on prior treatment and covariate history $(\overline{A}_{k-1}, \overline{L}_k)$. The causal diagram would include no direct arrows from any unmeasured risk factors U into treatment A_k at any time k. In this sequential randomized trial, the treated and the untreated at each time k are exchangeable conditional on prior covariate history $\overline{L}_k$ and treatment history $\overline{A}_{k-1}$. That is, sequential exchangeability $Y^g \perp\!\!\!\perp A_k|\overline{L}_k, \overline{A}_{k-1}$ holds for all times $k = 0, 1 \ldots K$, and we say that there are no unmeasured time-varying confounders. Under sequential exchangeability, we can obtain consistent estimates of the average causal effect of a treatment strategy via any methods that appropriately adjust for history $(\overline{A}_{k-1}, \overline{L}_k)$, such as standardization and IP weighting. The condition of sequential exchangeability $Y^g \perp\!\!\!\perp A_k|\overline{L}_k, \overline{A}_{k-1}$ can be slightly weakened. We can use single world intervention graphs (Richardson and Robins, 2013) to graphically derive these weaker sequential exchangeability conditions for static and dynamic treatment regimes.

Causal inference for time-varying treatments also requires a generalization of the positivity condition from the fixed version 'if $f_L(l) \neq 0$, $f_{A|L}(a|l) > 0$ for all a' to the sequential version 'if $f_{\overline{A}_{k-1}, \overline{L}_k}[\overline{a}_{k-1}, \overline{l}_k] \neq 0$, then $f_{A_k|\overline{A}_{k-1}, \overline{L}_k}[a_k|\overline{a}_{k-1}, \overline{l}_k] > 0$ for all a_k.' The definition of consistency of counterfactuals can also be generalized in a sequential fashion from the fixed version 'if $\overline{A} = \overline{a}$ for a given subject, then $Y^{\overline{a}} = Y$ for that subject' to the sequential version '$Y^{\overline{a}} = Y^{\overline{a}*}$ if $\overline{a}^* = \overline{a}, Y^{\overline{a}} = Y$ if $\overline{A} = \overline{a}, \overline{L}_k^{\overline{a}} = \overline{L}_k^{\overline{a}*}$ if $\overline{a}_{k-1}^* = \overline{a}_{k-1}$, $\overline{L}_k^{\overline{a}} = \overline{L}_k$

if $\overline{A}_{k-1} = \overline{a}_{k-1}$,' where $\overline{L}_k^{\overline{a}}$ is the counterfactual L-history through time k under regime $\overline{a}$. As always, causal inference requires well-defined interventions. Otherwise, a meaningful comparison of the treatment strategies is not possible.

Unfortunately, sequential exchangeability and positivity are not guaranteed to hold in observational studies. Achieving approximate exchangeability requires expert knowledge, which will guide investigators in the design of their studies to measure as many variables in $\overline{L}_k$ as possible. For example, in an HIV study, experts would agree that time-varying variables like CD4 cell count, viral load, and other joint predictors of treatment and outcome need to be measured and appropriately adjusted for. However, in observational studies the condition of sequential exchangeability cannot be empirically tested. Like for fixed treatments, causal inference for time-varying treatments requires the untestable assumption of conditional exchangeability – only now sequentially during the follow-up rather than at baseline only.

The Bias of Traditional Methods for Time-Varying Treatments

Let us assume for now that sequential exchangeability and positivity hold in our observational HIV study. That is, the measured time-varying confounders are sufficient to validly estimate the average causal effect of any treatment strategy. Then the question is what confounding adjustment method to use. The answer to this question highlights a key problem in causal inference about time-varying treatments: treatment–confounder feedback. When time-varying confounders are affected by prior treatment, traditional adjustment methods – stratification, regression, matching – may introduce bias. That is, even if we had all the information required to validly estimate the average causal effect of a treatment strategy, we would be generally unable to do so unless we used g-methods – inverse probability weighting, g-estimation, g-formula. The bias of traditional, stratification-based methods for time-varying treatments is conceptually identical to the bias of traditional methods for direct effects.

To illustrate this problem, consider again the HIV study depicted in Figure 1. Under this causal diagram, CD4 cell count L_1 is sufficient to block all backdoor paths between treatment and outcome (there is only one such path), so sequential exchangeability holds. Say that we want to estimate the average treatment effect of treatment strategy 'always treat,' $g = (a_0 = 1, a_1 = 1)$, compared with treatment strategy 'never treat,' $g' = (a_0 = 0, a_1 = 0)$ on the outcome Y. According to Figure 1, the true, but unknown to the investigator, average causal effect $E(Y^g) - E(Y^{g'})$ is 0.

The data analysis might start by computing the cumulative treatment variable $A = A_0 + A_1$, which can take 3 values: 0 (if the subject remains untreated at both times), 1 (if the subject is treated at time 1 only or at time 2 only), and 2 (if the subject is treated at both times). The treatment strategies of interest can then be expressed as 'always treat' $A = 2$, and 'never treat' $A = 0$. Because the average causal effect of interest is null, any valid method should estimate that the value of the difference $E(Y^{a=2}) - E(Y^{a=0})$ is 0.

A commonly used method to adjust for confounding is estimating the association between treatment and outcome in each subset – stratum – of the study population defined by L_1. Say that the variable L_1 can take only two values: 1 if the CD4 cell count is low, and 0 otherwise. To estimate the effect in those with low CD4 cell count, we would have to select (i.e., condition on) the subset of the population with value $L_1 = 1$. That is, we would compute the difference $E(Y|A = 2, L_1 = 1) - E(Y|A = 0, L_1 = 1)$. And similarly for the stratum $L_1 = 0$. But stratification can have unintended effects when the association measure is computed within levels of a variable L_1 that is caused by or shares causes with a component A_0 of the time-varying treatment.

Figure 2 shows that conditioning on L_1 – a collider – opens the path $A_0 \rightarrow L_i \leftarrow U \rightarrow Y$. That is, stratification induces a noncausal association between the treatment A_0 at time 0 and the outcome Y within levels of L_1. Among those with low CD4 count ($L_1 = 1$), being on treatment ($A_0 = 1$) makes it more likely that the person is severely immunodepressed; among those with a high level of CD4 ($L_1 = 0$), being off treatment ($A_0 = 0$) makes it more likely that the person is not severely immunodepressed. Thus, the side effect of stratification is to induce an association between prior exposure A_0 and U, and therefore between A_0 and the outcome Y.

Stratification eliminates confounding for A_1 at the cost of introducing selection bias for A_0. The associational differences $E(Y|A = 2, L_1 = l) - E(Y|A = 0, L_1 = l)$ could be different from 0 even if treatment has no effect on the outcome of any individuals. This bias arises from choosing a subset of the study population by selecting on a variable L_1 affected by (a component A_0 of) the time-varying treatment. The net bias for any particular summary of the time-varying treatment that is used in the analysis (cumulative treatment in our example) depends on the relative magnitude of the confounding that is eliminated and the selection bias that is created.

The same selection bias arises when fitting an outcome regression model for the mean outcome within levels of treatment history $\overline{A}$, summarized by the cumulative treatment A, and covariate history $\overline{L}$, which in our oversimplified example includes only L_1. One possible outcome regression model is

$$E(Y|A, L_1) = \beta_0 + \beta_1 I(A = 2) + \beta_2 I(A = 1) + \beta_3 L_1$$

where $I(A = a)$ takes value 1 if $A = a$ and 0 otherwise. That is, $I(A = 2)$ and $I(A = 1)$ are indicators – dummy variables – for values 2 and 1, respectively, of the trichotomous variable $A = A_0 + A_1$. When both β_1 and β_2 equal 0, the model estimates the conditional mean in those with $A = 0$, the reference value. The parameter β_1 is equal to the difference of conditional means $E(Y|A = 2, L_1) - E(Y|A = 0, L_1)$. This model assumes that the value of the difference is the same in the strata $L = 1$

Figure 2 Causal diagram of a study with time-varying treatment A_k and confounders L_k, and with conditioning on confounders affected by treatment. For simplicity, only the first two time points are shown.

Figure 3 Causal diagram of a study with time-varying treatment A_k and confounders L_k, and with conditioning on confounders that share causes with treatment. For simplicity, only the first two time points are shown.

Figure 4 Causal diagram of a study with time-varying treatment A_k and confounders L_k, and with conditioning on confounders that are on a causal pathway from treatment to outcome. For simplicity, only the first two time points are shown.

and $L = 0$. Some might want to interpret the associational parameter β_1 as the effect of 'always treat' $A = 2$ versus 'never treat' $A = 0$ within levels of the covariate L_1. Unfortunately, such causal interpretation is unwarranted because, as Figure 2 shows, conditioning on L_1 induces an association between a component of treatment and the outcome.

We said before that, in order to estimate the effect $E(Y^{a=2}) - E(Y^{a=0})$ without bias, we need to be able to estimate the joint effect of the treatment components A_0 and A_1 simultaneously and without bias. As we have just seen, this is something impossible to achieve using traditional methods such as stratification and outcome regression (and matching), even when data on L_1 are available. In the presence of treatment–confounder feedback, if we do not adjust for L_1, there will be confounding for the effect of A_1 on Y, and if we do adjust for L_1 by traditional methods, there will be selection bias for the causal effect of A_0 on Y.

Technically speaking, the bias of traditional methods will occur not only when time-varying confounders are affected by prior treatment, but also when time-varying confounders share an unmeasured cause U' with prior treatment, as shown in Figure 3 (Hernán et al., 2004). In this setting, conditioning on the collider L_1 opens the path $A_0 \leftarrow U' \rightarrow L_1 \leftarrow U \rightarrow Y$. For brevity, we refer to both settings in Figures 2 and 3 as treatment–confounder feedback.

Conditioning on confounders L_1 which are affected by previous treatment can create selection bias even if the confounder is not on a causal pathway between treatment and outcome. In fact, no such causal pathway exists in Figures 2 and 3. On the other hand, in Figure 4 the confounder L_1 for subsequent treatment A_1 lies on a causal pathway from earlier treatment A_0 to outcome Y, i.e., the path $A_0 \rightarrow L_1 \rightarrow Y$. Were the potential for selection bias not present in Figure 4 (e.g., were U not a common cause of L_1 and Y), the association of cumulative treatment A with the outcome Y within strata of L_1 could be an unbiased estimate of the direct effect of A on Y not through L_1, but still would not be an unbiased estimate of the overall effect of A on Y, because the effect of A_0 mediated through L_1 is not included.

In summary, adjustment for time-varying confounders is generally necessary when comparing treatment strategies that involve time-varying treatments either in observational studies or in randomized trials. Because traditional adjustment methods cannot appropriately adjust for time-varying confounders that are affected by treatment, g-methods (Robins and Hernán, 2008) are required to handle treatment–confounder feedback.

Abstract

This article discusses cross-time, multiple life-domain representations of life histories and their relationship to a defined set of outcomes. A primary objective is to demonstrate how to integrate numerical and narrative information derived from large data sets, where the individual history -or major segments of a whole life – is the basic unit of analysis. We distinguish bottom-up, or sequential aggregation strategies, from top-down, or partitioning strategies. The ideas and methods are illustrated in the context of health outcomes.

Longitudinal data analysis is a subspecialty of statistics in which individual histories use spaced en rules throughout for parenthetical dashes interpreted as sample paths, or realizations, of a stochastic process – are the primary focus of interest. A wide variety of scientific questions can only be addressed by utilizing longitudinal data together with statistical methods that facilitate the detection and characterization of regularities across multiple individual histories. Despite the stated focus on individual histories, most of the analytical strategies either invoke strong assumptions about stochastic dependencies across time and/or use variable-centered methods to study the influence of multiple covariates on process dynamics and its relationship to diverse outcomes. An exception to this pattern is the literature on growth curve analysis, where the full individual histories are modeled and frequently aggregated into categories of similar histories. This set of techniques, as currently constituted, has severe limitations when a study objective is to understand the interrelationships between multiple dimensions of a multivariate time series. Problems arise due to the utilization of interaction terms, as in regression analyses, which represent the imposition of a variable-centered idea in an inherently person-centered question.

The purpose of this article is to describe some person-centered methods that respond to the challenge of characterizing life histories, ascertained with longitudinal data, placing emphasis on the effective utilization of both cross-time and multiple-life-domain information. We motivate the methods and illustrate their use in the context of explaining how a variety of health outcomes occur. However, the methodological issues are generic and transfer to a wide range of problems in the behavioral and social sciences.

Motivation

Extensive empirical evidence documents associations between early and mid-life risk factors and later-life chronic disease and disability (Barker and Osmond 1986, Wadsworth and Kuh 1997). These findings generate considerable interest in understanding the subtle nuances of life histories that might explain how such outcomes occur. Broad-gauged interest in successful aging (Rowe and Kahn 1998), with particular emphasis on how some individuals manage to adjudicate effectively multiple difficult challenges, also suggests in-depth comparative studies of life histories. Detailed accounts of whole lives have previously been studied primarily as individual cases, with evidence presented in forms ranging from rich ethnographies to focused interviews and, in a medical context, from open-ended responses to structured inquiries by clinicians.

Complementing such narrative accounts of life histories are structured longitudinal surveys that contain – for each individual – hundreds, or even thousands, of responses to questions about experiences over time and across multiple life domains (Hauser et al. 1993, Power et al. 1991, Wadsworth and Kuh 1997). In principle, those interested in the impact of multiple facets of life histories on a given outcome(s) should be able to construct representations of whole lives from the survey responses. Despite considerable interest in this task across multiple disciplines (Elder 1974, Vaillant 1983), there has been a dearth of analytic strategies for producing representations of whole lives and for aggregating them into meaningful taxonomies that facilitate understanding of how given outcomes occur.

With these observations at hand, our primary objective is to describe top-down and bottom-up methods for constructing taxonomies of life history representations and use them as the basis for explaining how given outcomes occur. We will also emphasize the construction of narratives from numerical survey responses and their utilization as part of an analytical strategy to understand 'whole lives.' We illustrate the ideas and methods in the context of health outcomes. However, the methodological issues are quite general and by no means restricted to this class of outcomes.

Classes of Methods

The techniques discussed in this article are called person-centered in the sense that the individual life history is the unit of analysis. Within this broad class of methods are two categories of techniques called 'bottom-up' and 'top-down.' The bottom-up strategies begin with highly idiosyncratic individual histories, and the analytical steps then identify important commonalities and differences across lives, leading to

aggregation of histories into relatively homogeneous groups. Optimal matching (Abbott and Hrycak 1990), p-technique integrated with dynamic factor analysis (Shifren et al. 1997), and the integrated qualitative–quantitative aggregation strategy of Singer et al. (1998) are examples of bottom-up strategies.

Top-down techniques sequentially partition a heterogeneous population into progressively more homogeneous subgroups. Recursive partitioning (Zhang and Singer 1999), Grade-of-Membership models (Berkman et al. 1989), and the clustering methods of Bergman (1998) are generic examples of these methods.

A Bottom-Up Example: Understanding Psychological Resilience

The Problem

Among those who experience major episodes of depression in adult life, or earlier, some manage to subsequently regain high levels of well-being – that is, they demonstrate resilience. We ask whether those who show recovery have particular features that distinguish them from those who continue to suffer depression. An affirmative answer could suggest prevention strategies which, if applied early in life, might serve to bypass episodes of depression, or minimize their severity and facilitate recovery from them.

Longitudinal Data

The Wisconsin Longitudinal Study (WLS) began with a random sample of 10,317 men and women who graduated from Wisconsin high schools in 1957. Survey data were collected from the original respondents in 1957, 1975, and 1992/93. Telephone interviews were conducted in 1992/93 with 8 020 of the 1975 respondents, 6 535 of whom also responded to a mail survey. Data have been collected on respondents' family background, starting resources, academic abilities, youthful aspirations, social support, social comparisons, and the timing and sequencing of adult educational and occupational achievements, work events and conditions, family events, and physical and mental health. We focus on a subset of the 5 009 primary respondents who participated in all three waves of the WLS and who responded to questions assessing affective disorder and well-being in the most recent survey. The affective questions were administered to a randomly selected 80 percent of respondents. For each individual, there were responses on over one thousand variables covering all three waves of the survey and information across the multiple life domains indicated above.

The resilience criteria (see Singer et al. 1998) were satisfied by 168 women. There were 59 women who satisfied the depressed/unwell criteria. The analytical task is the development of a taxonomy of life histories for each group such that the characterization of any history is sufficiently nuanced to capture the richness of individual experience, but not so detailed as to represent only very few women. For a more broad-based discussion of resilience, using both narrative and numerical data on individual histories to the study of racial and ethnic inequalities in health, see Singer and Ryff (1997).

A Person-Centered Strategy

Construction of an empirical taxonomy of life histories requires a set of organizing principles – based on prior literature – that constrain the distillation of over one thousand responses for each individual into composite variables. Such composites are the basis for the ultimate representations of categories of histories. The following five principles were used to specify combinations of individual characteristics essential to explain how the outcomes come about.

a. Adversity and its cumulation over time has negative mental health consequences.
b. Advantage and its cumulation over time has positive mental health consequences.
c. Reactions to adversity or advantage influence the impact of life experiences.
d. Position in social hierarchies has consequences for mental health.
e. Social relationships influence the impact of life experiences.

These propositions are not new to the social sciences, mental health, or aging fields. What is new is the integration of them into an analytical strategy to guide life-history analysis. The methodology is usefully decomposed into five principle steps:

1. guided by the organizing principles, life history narratives are constructed for a sub-sample of cases from each outcome group (i.e., resilient and depressed/unwell);
2. abstracted chronological charts, each one representing the synthesis of several narratives, were constructed;
3. reduced response vectors, **b**, consisting of composite variables suggested by the chronological charts and individual variables whose rationale derives from the organizing principles are specified;
4. aggregates (categories) of histories, in terms of response vectors judged to be close to one another, are specified; and
5. tests of distinguishability are conducted.

Step (5) reduces to ascertaining whether or not the categories of histories characterizing the resilient women occur with low frequency in the depressed/unwell group and, conversely, whether histories characterizing the depressed/unwell women occur with low frequency among the resilient women. If the taxonomies of histories are to be a basis for explanation of the mental health outcomes, there should be distinguishability of categories of histories between the two groups.

Narratives

A small random sample (~10 cases) is selected from each outcome group, and a narrative biographical story is written about each individual. We adopt Stone's (1979) conception of narrative, defined as 'the organization of material in a chronological sequential order and the focusing of the content into a single coherent story, albeit with subplots.' Our rationale for writing narratives based on survey data (with over one thousand responses per individual) is that the human mind has difficulty processing enormous amounts of information in parallel (i.e., long lists of responses representing a single life), although it is well suited to process a coherent story (i.e., a

written narrative about a life) (Turner 1996). The use of narratives here is qualitatively different from their role when they are part of the raw data. Specifically, the construction of narratives – by the analyst and starting with numerical response data – is part of an analytical strategy. The narratives do not represent empirical data derived from focused interviews, recorded conversations, or text written by the respondents, but stories written by investigators to describe 'whole lives through time.' In generating the narratives, responses selected for inclusion were those expected to impact mental health, based on prior theoretical and empirical literature. The goal is to tell a life story in such a way that omitted information would make little or no difference for understanding the relevant life experiences preceding and predicting midlife mental health outcomes.

Abstract Chronological Charts

Two life histories can be aggregated and called similar, or even approximately indistinguishable, when the response vectors representing them are similar. At the level of individual cases, represented by raw response data on more than one thousand variables or by narratives, there is so much idiosyncratic detail that meaningful aggregation seems almost hopeless. However, via the organizing principles, it is possible to start with three or four narratives and begin specifying composite variables that ultimately lead to the specification of response vectors, some of which are sufficiently similar that they can be aggregated into a common category.

The composite variables are the initial basis for revised response vectors for all individuals that need to satisfy two criteria. First, the revised response vector for a given individual should provide for a nuanced summary of the person's life history as it relates to mental health outcomes. Second, the response vector should not be too idiosyncratic. The latter condition is essential if we are to aggregate life histories – represented as reduced response vectors – so that individuals with 'similar' response vectors can be grouped into common categories of histories.

Reduced Response Vectors

Guided by the abstract chronological charts, we specify a provisional reduced vector of variables, whose values for a single individual define the person's reduced response vector. The provisional reduced vector of variables will, clearly, represent all persons for whom we have constructed narratives. However, this is only a small sub-sample of a much larger population. We augment this group with 10–15 new cases for whom we do not have narratives. Their provisional reduced response vectors augmented by responses on additional variables that are clearly linked to the organizing principles are displayed. Visual examination of these augmented response vectors for the new cases AND those for which there are narratives serves to suggest new composite variables and revisions of those specified for the provisional reduced vector of variables. The result of this visual inspection and judgment is a new second-stage reduced vector of variables. We continue bringing in blocks of 10–15 new cases at a time, repeating the above step, and thereby iteratively refining the reduced vector of response variables until all cases for a given mental health outcome group have been examined. The final reduced vector of response variables, **b**, is the basis for initiating the formal specification of a taxonomy of histories.

Aggregation of Reduced Response Vectors: Pathway Specification

All variables are identified by binary codes in **b**. Next, we identify the longest AND statement common to at least 20 individuals. This identifies a set of response vectors – equivalently, a set of life histories – that exactly match one another on the components of the AND statement. If the components of the AND statement are distributed across the whole lives and they are interpretable as meaningful pathways to a given mental health outcome, then we have succeeded in aggregating a set of life histories into a well-defined group. For the resilient women in WLS, the binary coded version of **b** had 17 components, and the longest AND statement common to at least 20 individuals had seven components.

With an initial aggregate of histories at hand, we eliminate this group from further consideration and identify the longest possible AND statement characterizing at least 20 – and hopefully more – of the remaining men. In the WLS resilient women, this did not lead to a long enough AND statement that was sufficiently nuanced to characterize possible routes into episodes of depression, as well as the cumulation of advantage that would promote recovery. This led to specification of more complex Boolean statements that were both consistent with our organizing principles and represented the life histories of a substantial number of women. At least two strategies can be used for this specification. First, visual inspection of the 17-component response vectors revealed a group of 48 women, all of whom grew up in a household with at least one alcoholic parent AND who had a diversity of different forms of compensating advantage in adulthood (represented by logical OR statements). For a narrative description of the resulting Boolean statements, see Singer et al. (1998).

A more formally mechanized approach to this step – using, for example, Ragin's QCA software (1987) – would be to minimize the Boolean expression representing all women who are not in the first group identified via the 'longest possible AND statement criterion.' The resulting minimal Boolean expression would, hopefully, have clearly interpretable components that would represent distinct pathways – hence, additional members of the desired taxonomy of life histories – to given mental health outcomes. Although the analysis in Singer et al. (1998) proceeded beyond the first specification of an initial group by inspection and judgment, linked to organizing principals, we recommend application of both strategies en route to a final taxonomy. Indeed, as illustrated in Ragin (1987), minimal Boolean expressions that are not readily interpretable on a first pass through reduced response vectors often suggest recoding and construction of alternative composite variables that ultimately lead to a useful taxonomy.

Tests of Distinguishability

Having constructed a taxonomy of pathways for each outcome category – resilient and depressed/unwell in the present

example – it is necessary to demonstrate that the routes to any one outcome differ in important ways from the set of routes to a different outcome. To this end, we first ask whether the aggregate pathways for the resilient women differ from the pathways for the depressed/unwell population. In particular, we tabulate the frequency with which the resilient pathways occur in the depressed/unwell population. Conversely, we take the aggregate pathways representing the depressed/unwell women and tabulate the frequency with which those pathways actually occur among the resilient women. We expect to find that the resilient pathways are rare in the depressed/unwell population and also that the depressed/unwell pathways are rare in the resilient population. For example, 16 percent of the resilient women are on the pathway indicated above by the seven-component logical AND statement. Only 8 percent of the depressed/unwell have the same pathway ($p < .10$). Twenty percent of the resilient women are on the pathway where at least one parent is a chronic alcoholic AND there is a diversity of compensating positive experiences in adulthood. This pathway only occurs for 5 percent of the depressed/unwell population ($p < .05$). There are persistently negative-experience pathways in the depressed/unwell population that have no counterpart in the resilient group. Sharper discrimination occurs depending upon the particular application (see e.g., Zhao et al. 2000). The central point, however, is that assessment of distinguishability is important for making the case that there are, as hypothesized, qualitatively different routes to distinct mental health outcomes.

An Alternative Bottom-up Strategy

An analytical strategy that might serve as an alternative to what is put forth in the above example is optimal matching (Abbott and Hrycak 1990, Abbott and Barman 1997). Optimal matching derives from the literature on comparison of DNA sequences. It takes univariate time series for individuals and groups them together into sets of what are regarded as equivalent histories. The grouping requires the availability of a metric on the space of possible sequences (histories); and two sequences are defined to be members of the same group if their distance apart – in terms of the metric – is sufficiently small. To apply the automated optimal matching technique requires that input data be in the form of what we have called 'reduced response vectors.' The analogue of steps leading from more complex longitudinal data to this stage, as we have described above, must still be carried out for univariate time series prior to carrying out the formal aggregation step (Abbott and Hrycak 1990). Although optimal matching is a natural way to proceed in the construction of a taxonomy of histories, the problem with its implementation on cross-time, multi-life-domain data is that there is no obvious metric yet developed that is suited to the complex multidimensional time series corresponding to individual histories, as discussed in the above example. Furthermore, a single measure of distance between two multidimensional histories seems too coarse for decisions about what constitute equivalent histories. The strategy for aggregation of reduced response vectors – in the above example – uses information about multiple features of life histories. This suggests that any automated aggregation technique, analogous to optimal matching, should be based on a multidimensional measure on the space of histories.

Top-Down Methods

There is a considerable diversity of top-down, person-centered analytical strategies. A valuable review of both concepts and methods is contained in Cairns et al. (1998). One common strategy focuses on clustering techniques, where a critical input to the algorithms is a metric on the space of histories. Not surprisingly, applications of these techniques, which partition a heterogeneous population into relatively homogeneous clusters, have been restricted to low-dimensional data and rather simple summaries of histories. To reach the level of nuance and multi-domain representation of the kind we have discussed above requires a quite different set of measures of similarity of histories to be constructed than heretofore. This is an important research topic for the future.

Recursive partitioning (RP) classification (Breiman et al. 1984, Zhang and Singer 1999) is an automated procedure that fits trees to multi-dimensional longitudinal data such that pathways down the tree to a given outcome (terminal node) identify homogeneous sub-populations with common histories. Trees are constructed with the objective of maximizing ability to predict membership in the outcome categories. Each pathway down the tree ending in a given terminal node (identified, for example, with a health outcome) corresponds to a logical AND statement incorporating information across multiple life domains. Two or more pathways into the same terminal node are identified with a logical OR statement describing how that particular outcome occurred. The judgment of the investigator is required to determine whether all pathways to the nodes identified with a given outcome should be summarized by a single complex Boolean expression, or partitioned into two or more sets of pathways defining qualitatively different kinds of histories. Recursive partitioning (RP) algorithms could accept either the original raw response vectors or reduced response vectors, as described in the above example.

From our perspective, a limitation of RP for generating a taxonomy of life histories is the fact that the performance criteria and the splitting rules for tree construction are not constrained by substantive knowledge from any field of scientific inquiry (e.g., a set of organizing principles). Thus, pathways down the best predictive tree are not always interpretable within the knowledge of a given field. This disjunction between statistical performance criteria, based solely on numerical goodness-of-fit, and constraints on tree structure and splitting rules derived from extant scientific knowledge have proven problematic in past applications of RP (Levy et al. 1981, 1985), for example, applied RP to neurological assessments of comatose patients to predict which patients were likely to recover with moderate disabilities as opposed to remaining vegetative or dying within one year of hospital admission. The numerically best predictive trees were virtually never neurologically interpretable. Rather, inspection of 20+ nearly optimal trees led to selection, based on scientific judgment, of a prognostic tree that had interpretable pathways. For a start at more interactive – i.e., allowing the investigator to modify trees during the construction process on the basis of organizing

principles – and flexible strategies based on RP technology, the reader should consult Zhang and Singer (1999).

Conclusions

We have described a variety of person-centered methods for the analysis of longitudinal data. Particular emphasis has been given to a relatively new strategy – the bottom-up example – that takes a full complex individual history as the unit of analysis. The principal and novel features of this strategy are:

a. It includes the writing of narratives at the beginning and terminal stages of the analysis of survey data.
b. It is person- not variable-centered.
c. It produces pathways that represent aggregates of individual life histories.
d. It works simultaneously across multiple life domains.
e. It is capable of identifying multiple pathways to a given outcome.
f. It systematizes the decision making en route to delineation of the pathways.
g. It tests hypotheses about whole lives that are the integration of what is typically studied as separate pieces.

Point (a) underscores the importance of examining whole lives in story form as a means of comprehending the volume of detail that necessarily comprises human lives. Although point (b) is a clear objective in much of the life-history literature (e.g., Elder 1974, Magnusson and Bergman 1990), the lack of person-centered methodological tools has prevented investigators from proceeding to point (c). Attempts to get at aggregates have typically involved the use of variable-centered techniques, since these were available. However, the investigators mentioned above and many others were well aware that the lack of preservation of individuals as units of analysis severely limited the inferences they could draw about the dynamics of individual (or aggregates of individuals) change. Point (d) is conventionally dealt with, if at all, by variable-centered techniques. The bottom-up example strategy is, to the best of our knowledge, the first incorporation of multiple life domain information in a process of aggregation of whole life representations. Many investigators (e.g., Harris et al. 1990, Magnusson and Bergman 1990) have struggled with point (e); however, the absence of tools for aggregating whole life representations has prevented their delineating full pathways. Harris et al. (1990) set forth a template of several pathways to depression, and Magnusson and Bergman (1990) looked for 'patterns' connecting childhood problems with adult maladjustment. Nevertheless, their variable-centered empirical analyses (using logistic regression with interaction terms in the former, and cluster analysis in the latter) did not achieve the desired objective. What was needed was a person-centered methodology. Point (f) emphasizes the critical role of scientific judgment embedded in the progression of methodological steps, something that is an essential part of any data analysis, but is infrequently reported. Finally, point (g) carries hypothesis testing into the uncharted territory of whole lives.

Recommended reading for more detail on the person-centered methods emphasized in this article and on the integration of numbers and narratives to study whole lives, including narratives as data, see Singer et al. (1998), Singer and Ryff, (2001). An in-depth exposition of recursive partitioning, including online software, is contained in Zhang and Singer (1999). An instructive example of formal modeling of multiple-episode event history data is given in Heckman and Walker (1998) and a useful illustration of modeling of multivariate event history data, with both observed and unobserved covariates, is contained in Manton et al. (1987).

Longitudinal Data: Event–History Analysis in Discrete Time

Elja Arjas, University of Helsinki, Helsinki, Finland

This article is a revision of the previous edition article, volume 13, pp. 9063–9067, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

This article first gives a practical motivation for considering event-history models in discrete-time. The main point in the subsequent development is in explaining the structure of the corresponding likelihood function, including situations in which the considered individual status variables are related to covariates via a regression model. Finally, a brief description is given about how discrete-event history data can give rise to truly continuous time models, by applying Bayesian modeling for data augmentation.

The practical motivation for considering discrete-time models of event histories (Allison, 1982; Thompson, 1977) comes from the fact that such longitudinal data are often recorded and presented in a discrete-time form (*see* Longitudinal Data). Thus, for example, it is common to collect information on the values of considered individual status variables at regularly spaced time points and to report such measurements directly as the data. A time unit is then fixed, typically to be a day, a week, a month, or a year, thus creating a regular time lattice. A slightly different but related reason why event-history data often appear in a discrete-time form is that the event times themselves are reported in a rounded form. Then the events which happened inside a time interval of unit length are somewhat arbitrarily assigned to either of its end points or, in so-called *actuarial methods*, to the middle. As a consequence, the reported event times are often *tied*, with several individuals sharing the same value. As an example, one can consider the changes of a person's employment status during the work history, typically consisting of spells of employment and unemployment, and finally ending with a permanent transition to outside of the work force. In order to be completely accurate, the reporting might have to done day-by-day. More realistically in practice, it can only be done monthly, and then a number of different alternatives exist.

For example, one could directly report the employment status on the last day of the month. A drawback of such reporting would be that, if the status can undergo frequent changes, the status at the end of the month might be purely accidental and not represent the entire month in an adequate way. An alternative would be to set a threshold x and ask whether the person has been employed for at least x days during the month. Such a solution may not be completely satisfactory either, as a low value of x does not distinguish between people who were employed only briefly from those who were employed during the entire month, with a similar but opposite problem arising for a high value of x. Such problems are of less concern if changes in the status variable are less frequent (such as marital status), or even irreversible.

Discrete-Time Hazards

The main advantages from linking a statistical model directly with such data are that model construction becomes relatively straightforward, and that no special methods are required for dealing with the ties. For an illustration, suppose for simplicity that there are only two states for each individual, say *alive* and *dead*, and that the chosen time unit is one month. Then the lifetime T of an individual, in a discretized time scale, can be thought of as being determined by a sequence of Bernoulli trials, resulting in a sequence of 'zeros' as long as the individual is alive and ending with a 'one' for the month during which the individual dies. The basic element for setting up a corresponding statistical model is the conditional probability of recording 'one' in a unit interval given that all preceding intervals resulted in 'zeros', that is, the probability of death during the tth month for a person still alive after t-1 months (*see* Survival Analysis: Overview). Because of the discrete-time lattice used, such *discrete-time hazards* can be simply expressed as conditional probabilities:

$$h(t) = Pr(T = t | T \geq t) \qquad [1]$$

By applying the chain multiplication rule of conditional probabilities progressively for increasing values of t, one finds readily that the unconditional probability for the survival is given by the product

$$Pr(T > t) = \prod_{s=0}^{t} [1 - h(s)] \qquad [2]$$

Note that moreover

$$Pr(T = t) = Pr(T > t - 1)h(t) \qquad [3]$$

These are discrete-time analogues of the well known *exponential formulas* for the survival probability and density, respectively, which are valid in continuous time and express a lifetime distribution in terms of the corresponding *hazard rate* (see, e.g., Andersen et al., 1993; Kalbfleisch and Prentice, 1980). In fact, the exponential formulas can be obtained as limits when the time lattice used in the discretization becomes more and more dense, thereby making the discrete-time hazards $h(t)$ numerically small.

Regression Models and Likelihood Inference

When considering data consisting of lifetimes of several individuals, the number of such Bernoulli trials equals the total number of person-months at risk, and under natural independence conditions across individuals, a statistical model for the entire data can be formulated in terms of equally many

Bernoulli trials, with the corresponding discrete-time hazards depending on age. This gives rise to a simple likelihood expression of a product form, without that tied lifetimes in the data would be a problem. The structure of the likelihood remains essentially unchanged if the discrete-time hazards of the considered individuals depend on covariates, as long as the covariates are fixed in time. One is then dealing with a regression problem, in which the observed development of the response variables (lifetimes) is explained in terms of the corresponding realized covariate values in the data (*see* Survival Analysis: Overview). A convenient framework for considering such regression models, including the possibility of using standard software, is offered by *generalized linear models* (for a general account and references, see Fahrmeir and Tutz (1994), and for asymptotic properties of the estimators, see, e.g., Arjas and Haara (1987)). In the important special case of a *logistic link* function, if the considered time unit is short enough to make the discrete-time hazards $h(t)$ small and the intercept of the linear expression is allowed to depend on the interval, the model corresponds closely to the proportional hazards model of Cox (1972). If the covariates can themselves change in time, the same logic and structure of the likelihood can be used as long as the covariates are *external* (Kalbfleisch and Prentice, 1980) in the sense that their development can be thought of as being exogenous from the point of view of the studied event-history data of individuals.

This is because there is then no need for an explicit modeling of the process governing the covariate process, as the resulting contributions to the likelihood expression do not depend on the actual parameters of interest and can therefore be coalesced into a proportionality constant. The same logic applies if the individual event histories are right censored and the censoring mechanism is assumed to be noninformative. If the model also involves time-dependent *internal* covariates, special care is needed in modeling and inference to make sure that their development in time does not *confound* the regression problem and the corresponding conclusions, which are often given a causal form. The issue of confounding, in the case of sequential designed experiments, has been considered in a series of papers by Robins (e.g., Robins, 1997; Robins and Hernán, 2009). Sometimes, in order to give useful causal interpretations, it becomes necessary to build the regression model in two or more levels representing, for example, group level and individual level effects. For a recent contribution in this direction, see Barber et al. (2000). The same general ideas apply also in situations in which the considered status or response variables are no longer just binary. For example, the status of an individual could assume more than two possible values, and the same status could repeat itself many times during the follow-up. For example, as noted above, a person's employment status could first alternate several times between the states *employed* and *unemployed*, until it finally reaches the absorbing state *outside of work force* because of retirement. What is needed, however, is a convenient form of conditioning, which carries information about an individual's earlier history and present status and thereby influences the assessment of the discrete-time hazards associated with the future development, always by one time unit ahead. For an interesting case study, applying a variety of inferential techniques, see Fahrmeir and Wagenpfeil (1996).

Structure of the Likelihood

Let us now make this idea more explicit. Indexing the individuals in the data by $i \in I$ and denoting the value of the corresponding status or response variable at time t by $X_t(i)$, we are led to consider conditional probabilities for a transition from a state $X_t(i)$ at time t to a state $X_{t+1}(i)$ at a later time $t+1$. Denoting by $H_t(i)$ the pre-t-history of individual i, which contains all observations made on i up to and including time t, including the past values of $X_s(i)$ $(s \leq t)$ and of possible covariates considered in the analysis, the first task is to specify the conditional probabilities $\Pr[X_{t+1}(i)|H_t(i)]$.

The following natural conditional independence assumptions will then often be valid:

1. The variables $X_{t+1}(i)$, $i \in I$, are conditionally mutually independent given the collective pre-t-past $\{H_t(i),\ i \in I\}$ in the data.
2. Knowledge of the individual's own pre-t-history $H_t(i)$ is sufficient for predicting $X_{t+1}(i)$ in the sense that

$$Pr(X_{t+1}(i)|H_t(j), j \in I) = Pr[X_{t+1}(i)|H_t(i)] \qquad [4]$$

Under conditions (a) and (b), the likelihood expression arising from discrete-time event history data becomes a product of terms of the form $\Pr[X_{t+1}(i)|H_t(i)]$, where the product is taken over all individuals i and all times t. (A tacit assumption here has been that if the covariates registered in $H_t(i)$ are themselves time dependent, they are either exogenous or their evolution is modeled in a way which does not involve the actual parameter of interest.) This makes the statistical inference of the model parameters in principle a straightforward problem, for example, by applying maximum likelihood. If, moreover, the condition

3. Knowledge of the current state $X_t(i)$ is sufficient in the sense that

$$Pr[X_{t+1}(i)|H_t(i)] = Pr[X_{t+1}(i)|X_t(i)] \qquad [5]$$

holds, the model can be formulated in terms of a discrete-time *Markov chain* (see, e.g., Cinlar, 2013 and Markov Models and Social Analysis). Information contained in the observed past history $H_t(i)$ can then be stored into a covariate vector of a fixed length, and the likelihood becomes a product of transition probabilities $\Pr[X_{t+1}(i)|X_t(i)]$, again taken over both i and t.

In spite of the seemingly general applicability of such a discrete-time approach to likelihood inference, the following two conventions, both usually involving an approximation, seem necessary in interpreting such models. First, censoring and possible other forms of controlling the number of individuals at risk are always thought to happen at times which are integer multiples of the chosen time unit. Second, if the model involves time-dependent covariates which are used as regressors of the observed status or response variable, their measured values need to be interpreted as 'prevailing (constant) conditions for exposure' during each considered time interval of unit length (see Sandefur and Tuma, 1987). In particular, if the response variable can feed back and influence the values of the covariates, in order to save a causal interpretation of the regression model, the covariate values must be determined already at the beginning of each time interval, thus avoiding

the potential problem of conditioning on variables which are intermediate between a contemplated cause and the effect.

Embedding into Continuous-Time Models

Another, and perhaps a more serious, drawback from a modeling perspective concerns the interpretation of the discrete-time parameter. In almost any conceivable applied context, and corresponding the common human perception, time is viewed as being continuous. Based on this perception, and even in situations in which the data are in a discrete-time form, a more natural alternative for statistical modeling of event histories starts from the idea that there is a true underlying status process in continuous time, and that the recorded event-history (panel) data consist then of a series of measurements from this underlying process taken at a number of typically prescheduled time points. The term *current status data* is sometimes used to emphasize this aspect. The development of a person's true employment status, marital status, support of political parties, or presence or absence of a chronic disease, as functions of time, would be natural examples. Indeed, such individual status histories would be the focus of a statistical analysis if they only could be observed, while discrete-time event history data consist merely of incomplete information, typically drawn from a sequence of cross-sections of such histories. As a consequence of such imprecision, individual event histories in continuous time are generally unidentifiable from discrete-time data. In particular, the exact times of occurrence are then not recorded, and if the status of a person has changed back and forth within a unit interval, this possibility may not even become explicit in the data (see, e.g., Stasny, 1986). Nevertheless, it may be possible to embed the data successfully into a larger statistical model in continuous time. The fact that the individual underlying continuous-time developments cannot generally be determined uniquely from the data can often be compensated with some form of *data augmentation*. In other words, we can then consider an entire collection, or distribution, of sample paths which are consistent with the data. The practical solution may involve some form of simulation (multiple imputations), while a theoretical motivation to such techniques comes from Bayesian statistical inference. Exact numerical computations become quickly infeasible in practice, however. This leads to an application of sampling-based *Markov chain Monte Carlo* methods, in which the possible realizations of the individual processes are drawn by simulation (*see* Monte Carlo Methods and Bayesian Computation: Overview). Such data augmentation methods have been applied to data describing phenomena such as recurrent bacterial infections (Auranen et al., 2000) and influenza transmission (Cauchemez et al., 2004), but the same approach applies more generally to problems in which it is natural to relate discrete-event history data to underlying individual developments in continuous time.

Conclusion

Depending on the context, modeling of event-history data may emphasize more the *event times* at which some particular events of interest occurred, or the *states* in which some studied process happened to be at the times at which it was measured. To stress the former aspect, one often speaks of survival or duration data. The second aspect is similarly stressed by talking about repeated measurements or longitudinal data. When the time variable in the data and in the model is discrete, it may sometimes be difficult to make a clear distinction between these two basic forms. On the other hand, the likelihood expressions will be of the same canonical product form in both cases, so that likelihood inference will remain the same. Recommended reading on these and closely related issues include Allison (1982), Barber et al. (2000), Diggle et al. (1994), Kalbfleisch and Prentice (1980), and Sandefur and Tuma (1987).

This article is a revision of the previous edition article by R.B. Warnecke, J.A. Parsons, volume 13, pp. 9067–9071, © 2001, Elsevier Ltd.

Abstract

Maintaining a panel in longitudinal surveys requiring reinterviews of participants over time is the focus of this article. The consequences and correlates of panel attrition are reviewed, and strategies for retaining sample members throughout the interview period are offered. Specifically, a set of recommendations for the initial design of panel surveys and tracking respondents between interview waves in order to minimize bias due to attrition is offered.

Introduction

Panel studies involve the collection of data over time from the same sample of respondents. Unlike other forms of longitudinal studies, panels allow for the study of individual behavior change over time. However, because the same individuals are followed, there is eventual attrition, or nonresponse, after the baseline data collection wave. Attrition is either due to the researcher's inability to locate the respondent for additional waves of data collection, or when located, the respondent declines participation. Since the value of panel surveys is dependent upon the ability to study the same respondents at different points in time, reducing attrition is of major concern in social and behavioral research. Loss of respondents over time raises the possibility of bias if those who are lost to follow-up differ from those who remain in the panel on key dependent variables. Therefore, panel attrition can affect both the internal and external validity of the study (Cook and Campbell, 1979). In this article, the author reviews some recommended strategies for minimizing panel attrition with general populations. Some of the strategies depend on institutions like the post office whose functions vary from country to country. The information provided here is about the United States, but it is expected that much of it is adaptable to other countries. The recommendations discussed here for minimizing panel attrition apply mainly to population-based samples. Panel surveys with more hard-to-locate or high-risk populations (such as the homeless, drug users, or runaway youth) will require more specific, tailored strategies (Wright et al., 1995; Scott, 2004).

Factors Associated with Panel Retention

Panel survey success depends on location, contact, and cooperation (Lepkowski and Couper, 2002). Failure to locate a respondent after the baseline wave can be attributed to residential mobility. According to the 2009 American Community Survey, 15.4% of the US population aged 1 year and over lived in a different residence than 1 year ago (Ihrke et al., 2011). The majority (67%) moved within the same county, 17% moved to a different county in the same state, and 12.6% moved to a different state. Age is correlated with moving; the highest rates of residential mobility are found among those aged 18–29 years, and they decline as age increases. Rates of residential mobility also vary with race and ethnicity; they are the lowest for non-Hispanic whites (13.8%) and the highest among Hispanics (17.9%). People who rent their homes are more likely to relocate than those who own their residences. Nearly one-third of people living in rental units reported having moved in the previous year compared with 6.7% living in owner-occupied housing units. Understanding these correlates of residential relocation will help investigators plan for the level of tracking they will need to do during follow-up interviews, and also guide the amount of locating and secondary source tracking information that is collected at baseline. Including these variables as indicators at the baseline wave of data collection is important for postsurvey attrition assessment and weighting to adjust for it.

When respondent location is successful, contact is the next step. Difficulty in making contact with successfully located panel subjects is a greater factor in the first follow-up waves than in later waves (Lepkowski and Couper, 2002). Detailed information on the successful subject contact from the baseline wave (number of contact attempts, time and day of interview, etc.) can be used to increase successful contact at subsequent waves. Once contact has been established, the subject's cooperation is largely going to be based on past experience with the study: salience, perception of burden, and degree of 'panel fatigue,' which is the term used to describe subjects who drop out of longitudinal studies after several waves of data collection due to boredom or loss of interest in the study.

Study Design Features to Maximize Panel Retention

There are three main factors that will affect the degree of attrition in any panel study: (1) recruiting the respondent into the study; (2) successfully locating the respondent for subsequent interviews; and (3) maintaining the respondent's commitment to the panel.

Recruiting Respondents to the Panel

Plans for recruitment and retention should be developed at the time the study is designed and budgeted. They are as important as any other feature of the study design, but often do not get the

serious attention – and importantly, funding allocation – they deserve. Preplanning will ensure not only that there are sufficient resources to successfully recruit and retain the respondents, but also that the information needed to track respondents is collected during the baseline interview. It will also guide the selection of the sample size since this must allow for attrition if locating respondents is anticipated to be a serious problem. It may also affect decisions about the mode of interview, because certain segments of the population may not be available by one mode or another. For example, a longitudinal study of seniors may net few successful follow-up contacts via e-mail, whereas e-mail, Facebook, and other social technologies would be critical for college-aged populations.

Successful recruitment and retention can be enhanced with the creation of a recognizable identity for the study. A study logo and identifiable study title or acronym that is used in all correspondence (written and oral, including the study's Web site) and that appears on self-administered questionnaires, where applicable, have also been suggested as a way to create an identifiable image of the study for the respondent (Given et al., 1990). With the right population, a study Facebook page can also be used to provide general information and next steps for study participants.

Depending on the sample frame, an advance letter and/or advance e-mail should be sent to respondents at baseline, prior to the first interviewer contact, which explains the purpose of the study, and where they can go for further information (e.g., a phone number or study Web site, depending on the population). Clearly, advance letters or e-mails require that the investigator have these addresses for the population; if unavailable, they should be obtained at the baseline interview for follow-up purposes.

Locating and Tracking Respondents for Follow-Up Waves

Once respondents are recruited into the panel, several methods can be used to increase the likelihood of contact at designated follow-up waves. These generally can be classified into proactive, field-based, and centralized tracking efforts (Couper and Ofstedal, 2009). Attempts at locating the respondent should persist until a final disposition of the case can be ascertained for the purposes of calculating response rates.

The proactive approaches refer to the essential information that needs to be collected at each interview wave in order to increase the likelihood of locating them later. During the baseline interview, information should be obtained that will help locate respondents later. One invaluable resource is the secondary contact source. Secondary sources are usually one or two persons, not residing with the respondent, who will know how to contact the respondent at any point in time. At a minimum, the relationship of the secondary source to the respondent and that person's telephone number and e-mail address should be collected. Allow for the contingency that the subject may want to get their source's permission to share their contact information first; this will involve follow-up calls, and perhaps mailings, to ensure that the subject secured this information. A form in a postage-paid envelope could be left with the respondent to complete and mail back once they have received permission from their contacts.

In addition, during the baseline interview all respondents should be asked to provide their dates of birth, social security numbers (for use with credit-based tracking programs), and driver's license numbers. Depending on the population, respondents' e-mail addresses should also be collected as they can be used as an inexpensive means of tracking respondents. Note that the subject will need to be assured that this information will only be used for tracking and locating purposes. In addition, depending on the population, you can ask for the subject's permission to contact them via social media (Facebook and Twitter).

Even the most conscientiously designed study will not prevent respondents from being lost to follow-up. If all secondary source information does not lead to the whereabouts of the respondent, there are some field-based strategies that can be employed. In face-to-face studies, an excellent source of information about respondents comes from people who are connected in some way with the respondent. Roommates, neighbors, property managers, mail carriers, family, and friends might be available to assist in searching for, and contacting, a hard-to-find study participant. When finding the respondent through direct contact does not lead to complete or solid information, personal informants can sometimes provide essential information about how to reach the respondent, what kind of schedules they keep, and whether they have moved.

In addition to 'address correction requested' stamped on advance letter envelopes, a number of other useful services are available through the United States Postal Service (USPS) to improve mailing addresses and locate respondents who have moved. Through the Address List Correction Service, business and resident mailing lists can be submitted for correction. Services provided include cross-listing of names to which mail cannot be delivered or forwarded; correcting ZIP codes, house numbers, rural, or post office box numbers, street names, and suffixes; furnishing new addresses for customers who have moved; and adding building, apartment, suite, or room numbers when known. There is a minimum charge for correcting each submitted list, which can be arranged through local post office branches. In addition, the USPS National Change of Address (NCOA) program processes change of address data nationwide. The NCOA service is provided by private sector companies, certified and licensed by the USPS, who charge a fee for the service. These companies receive updated, computerized COA information on a regular basis. To search for lost or unlocatable study respondents, a file of names and addresses is submitted to one of the NCOA vendors, who search for matches in the NCOA. New addresses are provided when an exact match is found. Most other countries will have systems with many of these attributes.

Moreover, centralized tracking may also be useful in locating respondents. Property records, credit bureaus, and vital statistics databases may be accessed, usually for a fee. It is important to investigate these databases during the planning stages, not only to properly allocate fees in the budget for searchers, but also to ensure that the correct information is collected. Accessing public records is necessary for obtaining missing information about respondents. Public records contain data on births, deaths, marriages, criminal activity, military service, motor vehicle registration, and employment. Of particular use in panel studies that span a long period of time is the National Death Index,

maintained by the National Center for Health Statistics. For a fee, the index will match respondents with their file of deceased persons using the name and date of birth. The likelihood of a match increases if the social security number or middle initial is available. In some states, it is possible to search a Web site from the department of corrections to ascertain if any study participants have been incarcerated.

Retaining Respondents between Interview Waves

Being a member of a panel is burdensome for the respondent. Thus, it is critical to the successful maintenance of the sample that the relationship be reinforced between contacts.

Regardless of the duration of time between data collection waves, it is advisable to maintain contact with respondents every 3–6 months as resources allow, relative to the total length of data collection. Regular contact keeps the respondents engaged and reminds them of the value placed by the investigator on their participation. It also helps the investigator keep track of the respondent. The extent of the contact need not be more than the advance letter or a thank you note. Besides a friendly greeting and an expression of thanks for the respondents' participation, the content should include a reminder of the time of the next follow-up survey and a request for new contact information if the respondent has moved or will be moving. Investigators can also personalize the contact between interviewing waves by using birthday cards, holiday greetings, or other forms of written correspondence (Walton et al., 1998). These formats reinforce that the study staff is interested in and cares about the participants.

The Use of Incentives to Recruit and Retain Subjects in a Panel Study

Overall, the literature favors the use of incentives in cross-sectional surveys (Church, 1993; Singer et al., 1999), particularly prepaid, monetary incentives, to increase response rates; these results are generally consistent across all modes of data collections and different populations (Toepoel, 2012). Incentives are commonly used in longitudinal studies as well as a strategy for encouraging participation, given the respondent burden associated with repeated involvement and the value of the subject's ongoing participation to the researcher (Laurie and Lynn, 2009). Not only do they represent a concrete expression of appreciation to the respondent, but they also have the effect of keeping the respondent interested and involved over time.

The work reported by Singer et al. (1999) is also applicable to panel respondents. It suggests that informing the respondent at the start of the study that they will be offered an incentive for participation increases cooperation at later waves. Thus, at the conclusion of each interview, and before collecting the data that will help track the respondent at subsequent waves, it is useful to inform respondents that they will be paid an incentive for their future participation. However, it is important to emphasize that the respondent is not being paid for the data just provided. Rather, the incentive is a token of appreciation for having provided something that is invaluable and therefore cannot be purchased.

It is not uncommon for longitudinal surveys to increase the incentive amounts with each wave of participation, or to pay a bonus if all waves are completed. For longitudinal surveys that span several years, an increase in the incentive payment at each wave acknowledges cost of living increases and is a symbolic gesture to the respondent that their ongoing cooperation is valued and important (Laurie and Lynn, 2009). Anecdotal evidence also suggests that respondents are more likely to notify investigators of new addresses when they have moved if they expect an incentive, especially when the subject receives between-wave reminders from the investigator.

Summary

Panel retention is an important part of longitudinal studies that involve reinterviewing a cohort of respondents over time. While participation in a panel is a burden for the respondent, maintaining an unbiased panel is a challenge for the investigator. Thus, before such a project is undertaken, planning is critical and the level of effort and associated costs need to be considered from the outset.

A key aspect of a successful panel is the study design. The sample, questionnaire, and associated budget must all accommodate the need to recruit an unbiased panel and maintain their participation over a lengthy period of time. Recruitment involves attracting individual respondents to agree to participate in the baseline and to be followed for some period of time afterward. Locating respondents is critical to ensuring the continued quality of the panel data. Finally, recruiting and maintaining the panel will be facilitated if respondents develop a commitment to it. Ensuring that the panel is an unbiased sample of the population of interest requires effort to not only convince individuals to participate but provide sufficient information to enable the panel to continue.

Achieving a high level of cooperation to any survey has become increasingly challenging over the last decade; the Pew Research Center reports that their telephone surveys that would have had a response rate near 40% in the late 1990s was lower than 10% by 2012 (Kohut et al., 2012). A successful longitudinal study will require careful planning and budget allocation from the outset. Plans for follow-up must be established at the onset of the study so that not only all the relevant information is collected from the respondents as necessary resources are allocated, but also detailed nonresponse analyses can be performed. Without sufficient data on respondents, when they change residence or telephone, they are likely to be lost to follow-up, introducing bias into the data. Convincing respondents that they are important to the success of the panel and that the investigator values their participation ultimately helps reduce the cost of locating and following the respondents. Overall, participation in research is a process of exchange. Thus, it is important to show respect and consideration for the sources of the data.

Long-Term Potentiation and Long-Term Depression

Tammy L Ivanco, University of Manitoba, Winnipeg, MB, Canada

This article is a revision of the previous edition article by M. Ito, volume 13, pp. 9071–9074, © 2001, Elsevier Ltd.

Abstract

Long-term potentiation (LTP) and long-term depression (LTD) have been studied extensively as experimentally induced phenomena in the brain, and may share mechanisms with learning and memory, which most of us are more familiar with. Stimulation to induce LTP and LTD, an increase or decrease in synaptic strength, respectively, has indicated a sequence of overlapping molecular events from induction to long-term maintenance of the change in synaptic strength. Many studies have focused on the roles of *N*-methyl-D-Aspartate and mGluRs in LTP and LTD, and the subsequent intracellular cascades the receptors help control. LTP and LTD are associated with mechanisms that indicate a complex and flexible memory system, which is also dependent on the transition from simple to more complex connections at synapses. As the mechanisms in LTP and LTD parallel to those found with learning and memory, there is potential that LTP and LTD studies may reveal how we learn and remember, and how learning and memory may fail. Pharmacological manipulations that are used to study LTP and LTD may suggest potential drug treatment for brain disease and aging, and LTP/LTD stimulation protocols may become useful in the treatment of brain disorders, such as Epilepsy and Fragile X Syndrome.

Introduction

Long-term potentiation (LTP) and long-term depression (LTD) have been broadly studied in many brain areas and circuits. LTP and LTD are characterized by the persistent increase or decrease in synaptic strength, respectively. LTP, discovered in the early 1970s, met with much acclaim because it satisfies criteria proposed for a synaptic mechanism involved in learning and memory proposed in Donald Hebb's book "The Organization of Behavior." Hebb had suggested that learning and memory were the outcomes of the selective strengthening of synapses in response to activity. Later, theories on the weakening of synapses were also proposed, which could provide the basis for forgetting and general memory loss. As LTP and LTD have characteristics that mirror learning and memory, and are easily studied in the laboratory, they rapidly became popular models of synaptic plasticity. Evidence suggests the modification of connections throughout brain circuitry occurs in response to repeated experiences using LTP- and LTD-like processes. Whether LTP and LTD are actual synaptic processes underlying learning and memory remains to be determined, but research suggests many forms of memory rely on similar molecular mechanisms also used by LTP and LTD.

Generally, there are two approaches to inducing lasting change in synaptic connections experimentally to simulate the brain's response to repeated experiences. The first approach includes using high- or low-frequency electrical stimulation to induce LTP or LTD, respectively. The second includes causing activation though pharmacological or alternate methods to mimic the stimulation induction protocols used to induce LTP or LTD. More recently, LTP and LTD have been investigated as tools to assess and treat disorders and diseases of the central nervous system, particularly in transgenic mice. A number of neurological disorders and diseases appear to result from a loss or increase in synaptic excitability, resulting in changes in connections to and between brain regions. The ability to use both old and new technologies to influence synaptic strength is promising for altering synaptic plasticity and promoting better long-term outcome in disease and even with aging.

History

Virtually, all neuroscience textbooks highlight the basic rule proposed by Donald Hebb (1949), citing something like "When cell A repeatedly takes part in firing cell B, the connection between the two becomes strengthened." It took over 20 years for an instantiation of Hebb's Rule to be demonstrated experimentally, however. Per Andersen had laid some of the early ground work for the discovery with his studies on frequency potentiation (Andersen et al., 1966), in which repeated stimulation of the perforant path input to the dentate gyrus resulted in increased excitability of the granule cells lasting several seconds. Andersen and his graduate student (Andersen and Lomo, 1967) had found that basic frequency potentiation was insufficient to account for some of the plastic changes necessary for learning and memory because the enhancements were short lived, but the idea for trains inducing a lasting effect was evident (reviewed in Lomo, 2003). After Bliss joined the lab, the experimental support for Hebb's Rule came when LTP was observed (Bliss and Lomo, 1973). The two studied the effect of high-frequency stimulation in the *in vivo* hippocampus of anesthetized rabbits at synapses between the medial perforant pathway and the granule cells of the dentate gyrus. In this study, a stimulating electrode had been implanted into the perforant path and a brief, high-frequency train of electrical pulses was used to induce action potentials in the afferent pathway of the dentate gyrus. The result ensured coincident pre- and postsynaptic depolarization at the perforant path-dentate gyrus synapses – cell A repeatedly firing cell B – as described by Hebb for synaptic strengthening. Recording electrodes implanted into the cell body layer of the dentate gyrus recorded the synaptic response in the form of an excitatory postsynaptic potential (EPSP), induced by the activated population of

granule cells. These recording electrodes also revealed the lasting synaptic enhancement resulting from the tetanus (high-frequency stimulation pulses). In this preparation, LTP lasted between 30 min and 10 h. Bliss and Gardner-Medwin (1973) retested LTP in the awake and freely moving rabbit hippocampus, using similar parameters. In the chronically implanted preparation, LTP lasted between 1 h and 3 days, sufficient to allow for comparisons with short-term memory.

The phenomena of LTP represented an entirely new way to investigate plasticity in the mammalian brain. Ensuing experiments examining the intact hippocampus focused primarily on rats and mice. The development of the transverse hippocampus slice preparation, with the easy placement of electrodes in defined areas and patch clamp opportunities, resulted in the ability to experimentally focus on determining the rules for LTP induction and the molecular mechanisms of LTP, and subsequently LTD. An *in vitro* preparation, or slice preparation, requires the dissection of a very thin slice of brain tissue (most often hippocampal brain tissue) that is placed into chamber with oxygen and a cocktail of chemicals that keeps the tissue viable for several hours. Research has now demonstrated that LTP can be induced across the brain, in subcortical (e.g., Racine et al., 1983) and cortical locations (e.g., Ivanco et al., 2000), and even between these locations (e.g., Ivanco and Racine, 2000). Investigators considered the rules determined in LTP studies and sought out whether LTD followed similar rules. The answer is both yes and no.

Alger and Teyler (1976) found low-frequency monosynaptic stimulation between the perforant path and dentate resulted in a long lasting depression of the evoked response in hippocampal slice preparations. LTD has now been reported in other pathways of the hippocampus and cortex, *in vivo* and *in vitro* preparations (e.g., Froc and Racine, 2004). Since the first early reports of LTD, it has become clear that LTD can be divided into two types. The first type is LTD that is observed *de novo* in response to low-frequency stimulation. The second type is LTD that is observed only after the induction of LTP. Often the second category is called depotentiation, due to the enhanced response of the synaptic connections that must first be generated. Further, with depotentiation, the response does not depress beyond the baseline evoked response. There is some debate whether LTD is really a mixture of LTD and depotentiation.

Activity-dependent modification of synaptic connections is fundamental to the storage of information within the brain, but there may be additional considerations when studying plasticity consistent with how we seem to store information. Bidirectional modifications in synaptic plasticity are important in models of learning and memory, as they highlight both our ability to learn new information, but also forget or lose access to information that is no longer used. The ability of new and old information to interfere or help with learning indicates the underlying mechanisms must be very dynamic. The theory of metaplasticity (reviewed by Abraham and Bear, 1996), which can be thought of as a higher form of plasticity, suggests plasticity can be modulated or modified by prior synaptic activity. Evidence for an electrophysiological correlate comes from studies investigating the induction of LTP by a strong tetanus after first providing a weaker tetanus. Huang et al. (1992) reported that a weak stimulus delivered to the Schaffer Collaterals prior to a stronger tetanus inhibited LTP in the CA1 region of the hippocampus. They suggest that a low-level activation of the *N*-methyl-D-Aspartate (NMDA) receptors resulted in this inhibition of subsequent LTP. The low-frequency priming stimulus can also facilitate LTP induction by high-frequency trains if the priming tetanus is delivered at an intensity that is near the threshold for inducing LTP (Christie et al., 1995). The data suggest a complex interaction between low- and high-frequency stimulation. Further adding to this complexity, a priming stimulus has been shown to result in LTD. Christie and Abraham (1992) discovered an associative form of LTD occurred in the lateral perforant path to dentate gyrus pathway. Associative LTD only appeared when the priming, low-frequency stimulation was provided before and out of phase with the high-frequency stimulation, which alone would induce LTP. One of the general predictions from this metaplasticity argument is that the prior induction of LTP would also facilitate LTD. Indeed, synaptic depression in the form of LTD is more reliably produced in the CA1, if LTP is first induced (e.g., Staubli and Lynch, 1990). Exploring metaplasticity may actually prove valuable for noninvasive stimulation techniques for use in diseased or damaged brain. LTP and LTD allow for a set of dynamically altered connections, providing evidence for a very flexible memory system.

Induction

LTP and LTD induction is the sequence of early events that lead to the initial increase or decrease in synaptic efficiency, respectively. Racine et al. (1983) provided some of the first evidence that LTP in the hippocampus and other brain regions was not a unitary process, but involves a sequence of overlapping phases that rely on different mechanisms. Racine et al. (1983) defined an early LTP phase (LTP1, also commonly called E-LTP) lasting 1–2 h in the chronically implanted animal and a late phase of LTP (LTP2, also commonly called L-L) lasting about 5 days. The mechanisms involved in LTP induction are distinct from those involved in the phase that leads to persistent LTP and a sequence of synaptic changes parallel to the electrophysiological phases. Most of the research on the processes of LTP induction has resulted from the study of the CA3-CA1 synapses and the synapses between the medial perforant path and dentate gyrus, but generally the principles found in these synapses are consistent with other areas. Focus on these same synapses indicated, like LTP, LTD occurs as a sequence of overlapping phases. In both LTP and LTD, the postsynaptic NMDA receptors were found to be highly involved in the plasticity. Before discussing how receptors come into play, some of the characteristics of LTP and LTD may be helpful for understanding their actions and why particular receptors have been most well studied.

Input specificity and associativity fulfill criteria for an efficient memory system proposed by Hebb (1949) and also provide evidence for mechanisms underlying LTP and LTD. Independently stimulated afferent pathways demonstrate synapses that are located close together may still be independently potentiated or depressed, indicating input specificity. Using the same approach of independent stimulation, it

was found weak stimulation to a pathway that would not induce LTP on its own was sufficient when it was paired with stronger stimulation to a second pathway with synapses on the same target cells, indicating associativity similar to the associate nature of human memory first implied by Hebb. A third characteristic of LTP is cooperativity, which refers to the idea that when a train of stimulation (e.g., 200 Hz) is delivered to a pathway it induces depolarization in the postsynaptic side at the same time a new pulse reaches the presynaptic terminal. Cooperativity suggests that the synapse has a coincidence detector that both detects the postsynaptic depolarization and the next pulse from the stimulation train. The basis for cooperativity is the action and mechanism of the NMDA receptor. Like LTP, some forms of LTD also rely on the action of the NMDA receptor at many synapses.

The NMDA receptor is a glutamate receptor located on the postsynaptic terminal that is a calcium permeable channel activated by glutamate, but only when the postsynaptic membrane potential is sufficiently depolarized (reviewed in Bliss and Cooke, 2011). Depolarization allows for a magnesium ion blocking the channel to be expelled and glutamate released from the presynaptic terminal is bound, resulting in calcium and other cations into the synaptic terminal. The calcium influx into the cell through the NMDA receptor is essential for the induction of LTP and LTD. Indeed, the application of calcium chelators intracellularly prevents LTP (e.g., Lynch et al., 1983) and LTD (e.g., Mulkey and Malenka, 1992). The time frame for the NMDA-receptor mediated calcium influx is brief, but the LTP inducing tetanus (another term used for the stimulation train inducing plastic change) may activate receptors repeatedly, if the train is sufficiently long. The rise in intracellular calcium activates calcium-dependent enzymes. One of these is the calcium calmodulin-dependent protein kinase II (CaMKII), which has been noteworthy in the learning and memory literature, as well as the LTP literature. The NMDA receptor is actually a complex made of subunits and different LTD stimulation protocols seem to recruit the action of subunits differently. NMDA receptors are triggers for synaptic plasticity, but do not themselves determine the change in synaptic efficacy (reviewed in Collingridge et al., 2010). Thus, there must be other mechanisms that are involved in determining whether the resulting change following stimulation is an increase or a decrease in synaptic efficacy. One of the more recent discoveries is the incorporation of α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA)-type glutamate receptors into synapses that previously lacked them following coincident pre- and postsynaptic activity inducing LTP. Granger et al. (2013) investigated the AMPA receptor in LTP induction and found LTP was reduced when there was a decrease in AMPA receptors. LTP induces AMPA receptors located in a reserve pool until the LTP expression moves from the receptor level to changes in the synaptic structure. Some forms of LTD may reflect the removal of AMPA receptors from the synapse or internalization of NMDA receptors with low-frequency stimulation and chemically induced LTD, respectively (reviewed in Collingridge et al., 2010). Blockade of the NMDA receptor with antagonists prevent the induction of LTP, but have no effect once LTP is established, indicating an effect limited to the induction phase. NMDA-dependent LTP and LTD are the most commonly discussed forms of synaptic plasticity, but there are other forms of LTP and LTD that do not rely on the NMDA receptor. Froc and Racine (2004) found cortical LTP in the chronically implanted rat was dependent on the NMDA receptor, but depotentiation and LTD were not. Pairing of pre- and postsynaptic depolarization results in coincidence detection in the hippocampus and elicits LTP, but the same form of stimulation in the cerebellum results in LTD at synapses between parallel fibers and Purkinje cells, indicating alternate mechanisms in some synapses. Although a number of receptors have been tested, the mechanisms underlying induction of LTP and LTD in a range of brain areas continues to be investigated.

One characteristic that may lead to confusion in the LTP/LTD literature is related to how long the induction phase lasts. Although the induction phase is described as occurring prior to the expression and maintenance phases of LTP and LTD, the preparation being used has significant impact on how the timelines are described. In the transverse slice preparation, the induction period may be described as lasting minutes to about an hour. In the intact, but anesthetized preparation, the timeline for induction is similar to that of the slice (see **Figure 1**). The real difference occurs in the intact freely moving animal, with electrodes implanted and cemented in place so the animal can be anesthetic-free during induction, which can be done over a much longer period. In the case of the intact, freely moving animal, the induction phase for LTP may be minutes to few hours in the hippocampus (e.g., Racine et al., 1983), or even days for cortical LTP induction (e.g., Ivanco et al., 2000). The different preparations have provided support to the theory that hippocampal LTP is similar in nature to short-term memory, which is rapid, but information for long-term storage transferred to cortical areas through consolidation, and cortical LTP is similar in nature to long-term memory, which is more permanent, but requires more activation over time. Ivanco and Racine (2000) also found the structures between the entorhinal cortex, the origins of the perforant path, and the cortex could support LTP indicating an LTP-like mechanism could be used for consolidation.

A second challenge in reviewing the literature is defining the transition between induction, which seems mostly receptor dependent, and a more persistent form of synaptic change that is more dependent on protein synthesis and more obvious structural changes. Weeks et al. (2000) investigated morphological correlates of the induction phase by examining the synaptic morphology 1 h following LTP inducing stimulation in the chronically implanted rat. With this delay, the authors report no change in total synaptic number, but a change in the synapse profile, where more perforated (complex synapses) and irregularly shaped synapses were present in the dentate gyrus after perforant path stimulation to induce LTP. Concave synapses were found to be larger, as well. Although the preparation is different, Oh et al. (2013) found shrinkage in the size of individual spines within 60 min in response to low-frequency stimulation leading to LTD in hippocampal slice cultures from young rats. Structural changes in the window of the induction phase suggest an enlargement of synapses occurs with LTP and shrinkage of synapses with LTD. Thus, morphological changes can occur within the window defined as the induction phase.

Figure 1 Induction of cortical long-term potentiation (LTP) in the intact anesthetized preparation. An evoked potential from the rat cortex is shown in (a). Within (a), the population spike recorded in this potential is represented by A and the excitatory postsynaptic potential (EPSP) is represented by B. An evoked potential before (solid line) and after LTP induction (dashed line) is shown in (b). The time course for induction is shown in (c) with the arrows representing stimulation train delivery. LTP in this preparation is not immediate, but requires several trains to be observed.

Expression

Calcium detection mechanisms are involved in the transition from LTP and LTD induction to expression. The activation of calcium CaMKII and cyclic AMP (cAMP)-dependent kinase (PKA) is an essential step in the process of NMDA-dependent LTP in the hippocampus, and likely other areas where NMDA-dependent LTP is induced. The kinases are able to detect elevations in calcium and in turn phosphorylate proteins involved in expression of LTP, such as AMPA receptors. The glutamate receptor 1 (GluR1) subunit of the AMPA receptor is regulated by CaMKII and PKA. Lee et al. (2000) investigated the role of the GluR1 subunit on bidirectional communication using LTP and LTD induction protocols, but examined both naïve synapses and synapses that had a stimulation history. LTP induction in naïve synapses and depressed synapses increased phosphorylation to the CaMKII site and to the PKA site, respectively. LTD induction in naïve synapses and previously potentiated synapses led to dephosphorylation at the PKA site and CaMKII site, respectively. The data suggest LTP and LTD are not simply the functional inverse of each other, but that they have unique roles in modifying the AMPA receptor GluR1 subunits.

With the persistent activation of the detection mechanisms and kinase activation, a cascade of signaling events result in the production of new proteins and changes in gene expression (e.g., Dash et al., 1991) and allow LTP and LTD to have sustained expression beyond the first few hours. With the transition of early plasticity (E-LTP and E-LTD) to late plasticity (L-LTP and L-LTD), the signaling involved moves from the synapse itself to the cell nucleus, which is able to initiate the novel gene transduction protocols necessary for a longer term plasticity. This transition is accomplished by a complex cAMP signaling cascade that recruits PKA, mitogen activated protein kinases (MAPK), and cAMP-response element-binding protein (CREB), as well as a host of modulatory neurotransmitters including dopamine, serotonin, noradrenaline, and acetylcholine acting on their receptors.

Although most of the literature on the transition of LTP/LTD from an expression to a maintenance phase focuses on the processes occurring in the cell body, there have been recent findings that suggest that cells also have dendritic machinery that allows for a more selective set of alterations that would occur at the activated synapses independently. Weiler et al. (2004) found that the Fragile X Mental Retardation Protein

(FMRP) was involved in neurotransmitter-activated protein translations at the synapse. The translation of existing or new mRNA at polyribosomes located in dendrites or in the synapse would drastically reduce the time and need for additional proteins for plastic change at the synapse after activation. One of the more recent findings is the upregulation of micro-RNAs (miRNAs) in response to stimulation (e.g., Lee et al., 2012). The actions of the miRNAs are not fully known, but they may act to upregulate or downregulate targets to influence spine structure and function, and change plasticity locally at synapses.

Less research has focused on the structural alterations in this intermediate phase, than immediately after LTP induction or in the longer term. Weeks et al. (1999) investigated synaptic profiles 24 h after LTP induction in chronically implanted animals. LTP was not associated with an increase in synaptic number, but there was an increase in the proportion of presynaptically concave-shaped synapses 24 h following LTP induction. The concave synapses were smaller in the stimulated tissue than they were in control tissue and the synapses were more likely to be perforated (suggesting a more complex form). In second paper Weeks et al. (1998) used the same tissue, but correlated synaptic number with the degree of LTP induced. Although synapses per neuron had not shown up as significant in the initial study, synapses per neuron were significantly related to the degree of potentiation. Since potentiation varies in each animal dependent on electrode placement and the targeted synapses, it is noteworthy that as more LTP is induced, more synapses are present. Ivanco et al. (2000) examined spine density and dendritic arborization 24 h after the last tetanus of LTP inducing stimulation in the somatomotor cortex in chronically implanted rat. LTP expression in this area was correlated with greater spine density and alterations in the dendritic tree, which is consistent with anatomical changes induced by animal exposures to enriched environments. The data from the anatomical studies are consistent with a pattern of structural changes (reviewed in Weeks et al., 2001), whereby LTP induction, expression, and long maintenance are paralleled by an increasing level of overall complexity in the synaptic connections. There have been fewer studies of synaptic ultrastructure following LTD inducing stimulation.

Maintenance

CaMKII has been emphasized as one of the mechanisms involved in the transition to long-term maintenance for LTP. CaMKII can continue to phosphorylate itself, so it has the ability to remain active for a long time without other events occurring, even after calcium levels return to normal. In many ways, it is the memory within the system. Less, however, is known about the mechanisms leading to the maintenance of LTD.

Brain-derived neurotrophic factor (BDNF) is made in response to the MAPK and CREB signaling following presynaptic glutamate release. BDNF is a protein that regulates different cellular events, ranging from selection of neural progenitors to the terminal differentiation of dendrites and connectivity of neurons (Yoshii and Constantine-Paton, 2010). BDNF plays a role in both LTP and LTD, but not by playing an inverse role (reviewed in Bliss and Cooke, 2011). Early after it is made, BDNF (pro-BDNF) has the ability to bind to the tyrosine kinase B (TrkB) receptor and the P75 receptor. Activation of the TrkB receptor by BDNF binding encourages LTP induction. Binding of BDNF to the P75 receptor results in an alteration of the NMDA receptor, subsequently promoting LTD. The role of BDNF is complex, but it is a substance that has garnered a lot of attention as a key player, not just in LTP and LTD, but in learning and memory. Thus, BDNF has provided significant support for the theory that understanding mechanisms involved in LTP and LTD may translate into understanding mechanisms of learning and memory.

An atypical isoform of calcium-dependent kinase PKC, PKMzeta (PKMζ), may act locally to maintain LTP. PKMζ is expressed after LTP induction, but, like CAMKII, it continues to be active, even in the absence of calcium. Migues et al. (2010) found that PKMζ facilitates the maintenance of LTP by blocking a GluR2-dependent pathway and results in the increase of AMPA receptors in the synapse. The additional AMPA receptors at the postsynaptic site encourage additional synaptic transmission. Migues et al. also found evidence for a similar role in fear conditioning, indicating a common mechanism in LTP and learning. Further, they investigated the amygdala and hippocampus, so extended the role of this mechanism across the brain. Inhibition of PKMζ also resulted in a decrease in GluR2, but not GluR1 subunits. Downregulation of PKMζ has been implicated in LTD in the hippocampus 2 h after LTD induction (Hrabetova and Sacktor, 2001). The translocation of other PKC isoforms occurs transiently, but the downregulation of PKMζ is long lasting. PKMζ appears to be bidirectionally modified based on the type of stimulation and afferent activity. Hrabetova and Sacktor suggest that PKMζ may reflect one of the molecular correlates of a sliding threshold system triggered by stimulation where long-term dephosphorylation becomes associated with LTD and increased phosphorylation with LTP. The suggestion unifies a maintenance mechanism for both forms of synaptic plasticity, which would be biologically efficient.

The long-term maintenance of LTP and LTD may depend on long lasting structural alterations at synapses. In tissue collected 5 days after LTP induction in chronically implanted rats, the synaptic profile from stimulated animals indicated longer concave-shaped synapses and more perforations in synapses (e.g., Weeks et al., 2001). The longer concave surface area would support a greater number of NMDA receptors favoring a lasting and efficient synapse, following Hebb's rule.

Studying LTP/LTD in Human Brains

Many of the studies described stress activity-dependent plasticity found in laboratory animal brains. There has, however, been verification of similar forms of plasticity in human brains. One of the challenges for arguing parallel mechanisms in the human brain to the animal brain is that the bulk of the data from humans have been collected from tissue that may have been exhibiting neuropathology and was extracted following temporal lobe epilepsy. Key molecular signaling mechanisms and cells themselves are directly impacted by epilepsy. Despite this limitation, the human brain does exhibit activity-dependent plasticity we have seen in animals.

Beck et al. (2000) collected tissue that had been removed from patients that had drug-resistant temporal lobe epilepsy. A subgroup of the patients' hippocampi did not show severe damage. In this subgroup, LTP could readily be induced in the perforant path to dentate gyrus synapses by theta burst stimulation. A second subgroup with epileptogenic lesions outside of the hippocampus also showed LTP induced by stimulation. This LTP was confirmed to be NMDA dependent because a competitive NMDA receptor antagonist introduced into the slice bath blocked LTP. In patients with hippocampal cell loss or mossy fiber sprouting (a pathological correlate to seizures), but an extrahippocampal epilepsy focus, theta burst stimulation lower levels of NMDA-dependent LTP. Stimulation to induce a depotentiation effect 1 h after LTP, however, resulted in only a partial reversal of the LTP. Pharmacologically, increasing the cAMP concentration also resulted in a lasting LTP in the human hippocampal tissues, but LTP was lower than with stimulation. When the hippocampus was the primary source of the epileptic activity, however, LTP and depotentiation could not be induced, suggesting a severe impairment of the bidirectional communication. Loss of synaptic plasticity is a candidate mechanism contributing to the loss of declarative memory in humans and animals.

One of the treatments known to be effective in drug-resistant depression is electroconvulsive therapy (ECT), which has some parallels with LTP/LTD protocols. In this treatment, stimulation is delivered across the brain with the use of external electrodes, under anesthesia. There are theories as to how ECT might act on the brain to eliminate depression, but one of the most common theories is related to how ECT might reduce cortical excitability in a brain that has increased excitability. Kato (2009) has outlined the molecular cascades resulting from ECT and draws parallels with biochemical markers of LTD seen in animal studies. Thus, ECT may cause the induction of an LTD-like or depotentiation-like process in the active synapses in the cortex. In the clinic, a newer technology is potentially mimicking the effect of ECT for patients with depression. Low-frequency stimulation delivered through repetitive transcranial magnetic stimulation (rTMS) may provide a less invasive method, as it can be delivered without anesthesia and can be used over multiple sessions, and even at home with smaller direct current devices.

Epilepsy results from a hyperexcitability of synapses and may reflect an excessive level of LTP-like activation in glutamatergic synapses. For the same reason the rTMS works in depression, it may have a role to play in epilepsy treatment. Indeed, a method to induce LTD following endogenous LTP induction would have therapeutic benefits. One of the challenges for this type of treatment is related to the location of the primary epileptogenic focus. The coil device used to deliver rTMS is such that penetration into the brain is limited to cortical regions. For foci located in the cortex, rTMS may have more direct outcome, but for deeper foci, such as in the hippocampus, rTMS would be more limited. Data for the use of rTMS in epilepsy is not more fully discussed here, as there are mixed results in the literature, likely depending on the type of epilepsy and focus region. It would be expected the future research using rTMS and magnetic resonance imaging (MRI) to collect structural information and functional MRI (fMRI) to evaluate brain regions impacted by the epilepsy will reveal less mixed data on outcome.

In a review of the literature, Bliss and Cooke (2011) suggest that in intact brains, the readout of plasticity after activation is interpreted as synaptic plasticity, but not directly measured or without potential caveats. There have been debates about whether the synaptic plasticity seen in animal brains as a result of stimulation is paralleled in the human brain in the form of LTP and LTD. One of the future findings they indicate will be important for stimulation protocols to be more widely used in humans to induce LTP or LTD, is noninvasively induced plasticity that follows Hebbian rules. Longevity, input specificity, and associativity are key to a system that follows the rules Hebb laid out and would be necessary to move from LTP/LTD-like to discussing a noninvasive LTP/LTD in the human brain. Further to this is the identification of key synapses that are changed and how they are changed. The knowledge of the synaptic changes and mechanisms would also be important for using a noninvasive treatment for the plasticity-related challenges, the brain encounters both in disease and aging, but may also lead to more targeted pharmacological treatments when noninvasive techniques would be insufficient to recover lost or impaired function.

Putative Roles in Disease and Memory Impairment

Parallel investigations of LTP and memory are a major tool for examining the relationships between synaptic plasticity and memory. There is less investigation into the role of LTD in learning and memory, but one of the reasons for this is that many of the mechanisms involved in LTD and inhibitors of LTD also impact LTP, contributing to a less clear specific role of LTD. Understanding the molecular underpinnings of LTP and LTD in models may translate into a greater understanding of pathogenesis of disease.

Alzheimer's disease (AD) is a progressive neurodegenerative disease characterized by cognitive decline and loss of memory function over time. Additional characteristics include cortical atrophy, neuronal death, neuroinflammation, synaptic loss, and deposits within cells (neurofibrillary tangles) and the amino acid peptide amyloid-beta (Aβ). Although there has not been a disease-modifying drug developed, there has been significant discovery related to AD pathogenesis and how neuronal synapses are impacted by disease progression. Koffie et al. (2011) review the lines of evidence supporting the theory of alteration in amyloid processing leading to AD including the relationships between the Aβ precursor protein (APP) and trisotomy 21 (Down syndrome), and between Aβ and familial early onset AD. Further, Aβ in its oligomeric (multiple polymer) state may be toxic to synapses by inducing a partial blockade in NMDA receptor currents, changing calcium entry, promoting LTD over LTP, and inducing a cascade resulting in the internalization of NMDA receptors to inhibit future LTP. The long-term effects of Aβ would include a morphological change whereby spines would be inhibited from the alterations associated with LTP. Transgenic mice with an APP mutation have increased Aβ and generally have dramatic cognitive impairment. Although at physiologic levels Aβ would not lead to synaptic dysfunction, higher levels would lead to the clinical manifestation of AD. At low levels, Aβ may promote LTP and function, but higher levels lead to synaptic inefficiencies and

changes in the morphology, potentially leading to elimination of synapses, and later neuronal loss.

Neuroinflammation is a characteristic of AD, but neuroinflammation also increases in the healthy brain when an individual ages. Cytokines are immune system molecules that communicate between the immune system and brain. Unfortunately, inflammatory cytokines may also be one of the key contributors to the deficits in synaptic plasticity identified in aging rodents (reviewed in Lynch, 2010). One of the findings in aging rats is that as a rat gets older, there is less LTP. Inflammatory cytokines may impair the ability of aging animals to sustain LTP. Activated microglia are responsible for the release of cytokines, chemokines, and neurotrophins (e.g., BDNF). An important consequence of the release of inflammatory cytokines is a change in the brain that can profoundly effect behavior including a modulation of hippocampal and cortical learning and memory in the rodent (e.g., Larson et al., 2007). Lynch (2010) indicated that inflammatory cytokines introduced directly and indirectly into the brain influence LTP in the perforant path to dentate gyrus synapses, decreasing LTP. Further, impairment in LTP was directly in proportion to the level of inflammatory cytokines and inversely related with noninflammatory cytokines. Lynch was able to make a strong case for the causal link between microglial activation and impaired LTP, but also for the ability of inhibition of microglial activation to partially rescue LTP. Understanding how microglial activation inhibits plastic change may facilitate the discovery one of the most beneficial treatments, a treatment for the cognitive decline and loss of flexible learning that occurs with aging.

Cognitive impairment is a feature in many genetic brain disorders. Fragile X Mental Retardation Syndrome (FXS) is the leading inherited cause of mental retardation. In this disorder, an extension occurs to a CGG island of the Fragile X Mental Retardation 1 (FMR1) gene. The expansion to over 200 repeats leads to hypermethylation of the gene and a reduction or elimination in FMRP through transcriptional silencing. FMR1 knockout mice show learning deficits and hyperactivity and appear to represent a good model of the human disorder (Dutch/Belgium Consortium, 1994). These mice also exhibit protein synthesis independent LTD mediated by a group of mGluRs, which may also account for the abnormally long and thin dendritic spines seen in both the mice and the human population with the disorder (reviewed in Irwin et al., 2000). LTD-like processes mediated by mGluRs may contribute to the learning and memory problems in FXS.

The Fragile X premutation is a trinucleotide expansion in the CGG island of 55–200 repeats on the FMR1 gene. It was widely thought that the premutation carriers were not cognitively impaired, but this may not be the case. Hunsaker et al. (2012) investigated an animal model of the premutation to the FMR1 gene that contained 70–198 repeats. Increasing CGG repeats modulated the induction of LTP, LTD, mGluR1/5 LTD, and behavioral tasks that required spatiotemporal processing. Although an increasing number of CGG repeats was associated with impaired plasticity, the plasticity once induced did not show any difference in expression. Additional research is necessary to discover the mechanism underlying the relationship between CGG repeat number and impairment, to more fully explain the expected outcomes on plasticity and cognitive function.

Conclusions

Since the discovery of LTP in the hippocampus, a substantial amount of progress has been made to understand bidirectional plasticity in the brain. Most of the data has focused on the hippocampus, but many studies extend the findings on plasticity to other areas of the brain suggesting that some of the mechanisms that have been found are pervasive throughout the brain. LTP and LTD are a result of the activation of postsynaptic receptors that mediate synaptic transmission. The signaling cascades often suggest a unitary system that has flexibility to result in both LTP and LTP depending on the induction stimulus, but not in always in a reverse manner. Novel pharmacological and genetics approaches have allowed for a greater understanding, but also do much to highlight the role of an LTP- and LTD-like process in both health and disease states, as well as the role stimulation may play in interventions.

Lorenz, Konrad (1903–89)

Wolfgang M Schleidt, University of Vienna, Vienna, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Konrad Lorenz, cofounder of ethology (the study of the biology of organism behavior), ranks among the most important stewards of Darwin's heritage. A stern critic of the vitalistic concept of instinct and of the behaviorists' doctrines of the 'empty organism' that is predominantly environmentally controlled, Lorenz advocated a bottom-up analysis of behavior, stressing the importance of observation and inductive reasoning. This led to the discovery of a basically modular structure of behavior including 'fixed action patterns' controlled by internal variables and external 'key stimuli' coordinated by specific 'innate releasing mechanisms.' Learning occurs on these modular levels, e.g., as in 'imprinting.' Lorenz became one of the founding directors of the Max Planck Institute for Behavioral Physiology (Seewiesen), the leading institution for behavioral research in Germany. Lorenz, Niko Tinbergen, and Karl von Frisch shared the 1973 Nobel Prize for Medicine 'for their discoveries concerning the organization and elicitation of individual and social behavior patterns.' After his retirement, Lorenz returned to his native Austria, continued his work on graylag goose's social behavior and in evolutionary epistemology, and became an influential opponent of nuclear power and environmental degradation.

Biography

Family

Konrad Zacharias Lorenz (born 7 November 1903 in Vienna, Austria) grew up within the upper crust of pre-World War I Vienna: his mother Emma (née Lecher) from a family of writers and scientists; his father, Adolf Lorenz, world-renowned orthopedic surgeon, Nobel Prize nominee (Lorenz, 1936). Konrad spent his formative years in Vienna and at his family's country estate in Altenberg on the banks of the Danube. At that time, the river was still lined by large tracts of virgin riverine forest, and his inquisitive mind became fascinated by nature. He became a passionate observer and skilled caretaker of any swimming, crawling, or flying creature. These interests did not interfere, however, with his early socialization into the network of learned relatives and their friends (e.g., Karl Popper).

Education

After visiting a 'progressive' elementary school, he was sent to the esteemed *Schottengymnasium*, where his biology teacher, an enthusiastic Darwinist, introduced him to evolutionary reasoning. At his father's suggestion, he began to study medicine at Columbia University, New York, in 1922. Homesick, especially for his wife-to-be, he continued his studies in Vienna, receiving his Dr med. degree in 1928. During his first appointment as *Demonstrator* (eqivalent to assistant professor) at the Department of Anatomy, University of Vienna, he studied zoology (J. Versluys), paleontology (O. Abel), and psychology (K. Bühler, his assistant E. Brunswik); he received his Dr phil. degree in 1933.

Scientific Career

Lorenz's meager salary as *Demonstrator* and his wife's (Margarethe née Gebhardt) income as physician at a local hospital provided just enough to raise their family. Lorenz was always short of funds for the private research facility he had established in Altenberg. His negotiations with the (German) Kaiser-Wilhelm-Gesellschaft for funds to create a special institute for behavioral studies date back to 1937, but at the outbreak of World War II this project was shelved. In 1940, E. Baumgarten (a nephew of Max Weber and a pupil of J. Dewey and, hence, a representative of the pragmatist school of philosophy) accepted the famed chair of philosophy at Königsberg University, once occupied by Immanuel Kant, and looked for a biologically oriented psychologist who, at the same time, was interested in theory of knowledge to share with him the prestigious appointment. O. Koehler and E. von Holst became the matchmakers, and Lorenz was chosen (Lorenz, 1974; Leyhausen, 2000; Burkhardt, 2005).

One year later, however, Lorenz was drafted into the German Army as a motorcycle rifleman (in his papers he had not mentioned his medical training because of his limited experience with patients, and stressed only his proficiency in motorcycle racing and repair). When the authorities discovered that he held a medical degree and was a professor of psychology, he was assigned to a unit of the *Heerespsychologie* (Army Psychology) in Posen. Two months later, however, this unit was dissolved, and he was transferred to the Posen Army field hospital for neurology and psychiatry, where he worked as *Unterarzt* (medical noncommissioned officer (NCO)) in a unit of 285 beds with patients suffering from war injuries, psychoses, and psychosomatic disorders. During a field assignment on the Russian front in 1944, he was captured by the Red Army. After that, he served in various POW camps as field surgeon until his release in 1948.

In post-World War II Austria, career prospects for a biologist were worse than ever, while in Britain Lorenz's colleagues became especially interested in the Darwinian approach to behavioral studies. Niko Tinbergen became reader at Oxford University and, in 1950, Lorenz received a similar offer from the University of Bristol. German colleagues, notably E. von Holst and G. Kramer, both meanwhile directors at the newly founded Max Planck Institute for Marine Biology (Wilhelmshaven), were able to revive the old project of an institute for behavioral studies.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61078-4

A matching offer was made, and Lorenz accepted the appointment as head of a small behavior research unit in Buldern, Westfalia, founded in spring of 1951 as precursor to a special Max Planck Institute for Behavioral Physiology. Construction started in Seewiesen, Bavaria in 1955, and the institute opened in 1958; Lorenz was Director of his own division there until he retired in 1973.

Retirement

Upon retirement, Lorenz returned to his home in Altenberg, Austria. Shortly thereafter, he was awarded, together with Niko Tinbergen and Karl von Frisch, the 1973 *Nobel Prize for Medicine*. During retirement, he tidied up his work on evolutionary epistemology, on the social behavior of graylag goose and reef fishes, and became an eloquent spokesman for environmental conservation (Schleidt, 1988). Lorenz died in Vienna on 27 February 1989 at the age of 85 and was buried near Altenberg at St. Andrä-Wördern cemetery (Wuketits, 1990).

Contribution to Knowledge

Lorenz, cofounding with Niko Tinberger the science of ethology as 'the study of the biology of organism behavior,' ranks among the most important stewards of Darwin's heritage of the twentieth century. In the 1930s and 1940s, most psychologists, sociologists, and biologists tried to understand behavior within the framework of Aristotelian philosophy, theology, Marxism, or Behaviorism. Lorenz, on the other hand, viewed behavior as playing a central role in the process of evolution, and shaped primarily by 'natural selection,' rather than by learning. By applying the methods of comparative morphology and paleontology to the study of 'species specific' behavior, he created a scientific approach that rapidly provided a wealth of data and new insights (Lorenz, 1931, 1932, 1950b, 1965b, 1978). Contrary to the claim of his critics, Lorenz ignored neither the conventional schools of thought nor their observations, but was cautious in accepting their theories and conclusions. For example, he never denied the importance of environmental factors in learning, but he challenged the behaviorists' claim that innate behavior was restricted to only a few basic vital reflexes. In fact, he emphasized especially the interlocking of modular innate and learned behavioral (e.g., as in 'imprinting,' Lorenz, 1935; of the two alternative channels through which information can enter a living system, Lorenz, 1961, 1965b).

Observation as Research Tool

Fundamental to Lorenz's approach to behavior is his rigorous adherence to the doctrine of *induktive Naturwissenschaft* (inductive natural science; Lorenz, 1942, 1959, 1978): first establish a solid base with meticulous observations, supported by objective records (photos, film), tainted as little as possible by theories, and – only after a solid data base (*Induktions-Basis*) has been established – let patterns emerge from the data. He became a pioneer of scientific cinematography (Lorenz, 1950a, 1952; Schleidt and Oeser, 2011) and was founding member of Encyclopedia Cinematographica (Wolf, 1967).

Behavioral Modules

Lorenz considered behavior to be composed of basic modules of classical reflexes, species specific *Instinktbewegung* 'fixed action pattern' (FAP) (in later years *Erbkoordination*, *erbkoordinierte Bewegung* (1978) (in English: 'fixed motor pattern')), specific circuits for the environmental control of reflexes and FAPs, which were 'innate releasing mechanisms' or IRM (*angeborener Auslösemechanismus*), 'appetites and aversions' (*Stimmungen*), etc. Such modules provide each organism with basic behavioral skills to navigate within its environment, detect necessary resources, avoid danger, and interact with conspecifics. Learning can enter in various ways at the level of each of these modules, e.g., in the case of a reflex as 'conditioned reflex.'

This FAP/IRM dyad is basically an extension of the classical stimulus–response concept, enhanced by several new features because the classical reflex, activated only by a specific external stimulus, cannot account for the observation that "a healthy animal is up and doing" (as W. McDougall so aptly remarked). Consequently, the spontaneous nature of behavior, in general, and especially in many typical FAPs (locomotion, courtship behavior, certain types of bird song, etc.) became a topic of special interest (FActionP). FAPs constitute much more complex patterns than any of the classical reflexes (FAPatterns), and particular spatiotemporal parameters of FAPs are highly stereotyped within any one species (FixedAP), but different between species. Lorenz exemplified the complex interaction between internal and external variables in his 'psychohydraulic' model (1950b, 1978), and applied this reasoning to explain the control of aggression in animals and humans (1963).

It was basically for this work on behavior modules, which are central to ethology, that Lorenz, Niko Tinbergen, and Karl von Frisch shared the distinction of winning the 1973 Nobel Prize for Medicine "for their discoveries concerning the organization and elicitation of individual and social behavior patterns."

Ethograms

Given the existence of species specific behavior, a behavioral study of individuals of any given species starts with an assessment of the modules of its behavioral repertoire, working toward the open-ended task of a complete 'ethogram' of that species. Lorenz had already touched on this in his first publication (1931), and a decade later published an exemplary comparative study of the courtship modules of ducks (1941b). He delayed publishing of his ethogram of the graylag goose until 1988 … as a sort of swan song.

The Innate Forms of Possible Experience

This heading is a translation of *Die angeborenen Formen möglicher Erfahrung*, the title of (Lorenz's, 1943) seminal paper dealing with the evolution of cognition, as a new paradigm. The results of many years of research into 'learning' – from the classical curves of learning and forgetting by I. Pavlov and E.L. Thorndike – indicate that it is a slow process. If an animal's survival depended solely on learning, it would be dead long before it had completed its first set of learning trials. Thus, it

should not be surprising that an animal, entering into its world, is equipped with: (1) certain 'innate' skills (behavior patterns to satisfy vital needs and escape danger), and (2) 'a priori knowledge' to detect essential features of resources and danger – innate in the sense that particular patterns of behavior or relevance of particular environmental features are available prior to individual experience. In other words a reflex, FAP, or IRM not only enables survival enhancing action, but it also constitutes organismic 'knowledge' about the environment and its contingencies to which that individual's ancestors had been exposed in the evolutionary process (Lorenz, 1941a, 1943, 1953, 1965b, 1973, 1978).

Imprinting

This peculiar process of forming an irreversible association between a behavior pattern and a 'stimulus' (object), without any reward other than the presence of that object, has been used for ages in animal breeding, and noted in the literature, but Lorenz was the first to recognize imprinting's far-reaching theoretical significance (Lorenz, 1935, 1965b, 1978).

Nature–Nurture

Much ink has been spilled on this duality, not much because of any intellectual challenge posed by these two concepts, but because of deeply rooted beliefs, religious or political, touching upon free will, accountability, and fate. Lorenz was attacked early on for his use of 'innate' as though he had excluded the possibility of learning, while all he suggested was that innate behavior was essential for the survival of individual organisms. Early on, he pointed to the intertwining of innate and learned behaviors (e.g., *Trieb-Dressur-Verschränkung*, drive-training-interlacing 1935) and, with imprinting, provided a splendid example of such a process; an example that was ignored by the ruling psychologists of his time. He was attacked relentlessly for defending the concept of innateness, despite numerous attempts to respond to his critics (1961, 1965b, 1978, etc.).

Epistemology

"Philosophy is the academic abuse of those human potentials which have evolved by natural selection for the individual's survival in his struggle with the daily contingencies of his world." This definition, attributed to Lorenz's mentor O. Heinroth, encapsulates the insight that human ability to acquire knowledge is not merely a matter of the reasoning individual *Homo sapiens* within a literate society, but is based on a long, evolutionary process, preceding the emergence of humanity by millions of years. Lorenz, having been elevated to Immanuel Kant's former chair in Königsberg in 1940, and facing the challenges by contemporary philosophy, and specifically by resident neo-Kantians, took a radically new approach to Kant's concept of a priori (Lorenz, 1941a, 1943), pioneering what is now called Evolutionary Epistemology (Popper, 1972; Vollmer, 1980). The most detailed discussion of this is contained in his posthumously published *Russian Manuscript* 1944–48 (1992), written with the fresh memories of his encounter with Kant's Königsberg in mind, while a more concise discussion can be found in the English edition of his textbook (1978/81).

Moral-Analogous Behavior, Human Morality, and Environmental Awareness

Lorenz, throughout his life, struggled with his belief that morality could well have an evolutionary basis (as he had shown convincingly for the evolutionary basis of cognition in his evolutionary epistemology). He coined the term 'moral-analogous behavior' (moral-analoges Verhalten): special behavior that channels the individual's selfish struggle for its individual existence and reproductive success into an altruistic contribution for the good of its community. Based on his observations of a variety of highly social animals, Lorenz noticed that domesticated forms had lost certain elements of their moral-analogous social behaviors, which their wild ancestors had evolved as essential part of their sociality. Lorenz concluded, by analogy, that human evolution in general, and especially our own modern civilization, has led to comparable domestication effects ('self-domestication'), which have become mixed blessings. Modern humans have freed themselves from the firm guide of instincts and consequently have more freedom to learn and to make their own choices, but they also have lost some of their instinctive inhibitions to inflict damage to, and even kill conspecifics to an extent not known in any other species (1940, 1943, 1963, 1983).

In his early papers, Lorenz proposed to counter these dangers to humanity with eugenic measures (before the atrocities of Hitler's Germany, eugenics was a widely respected field, especially in England and the United States), especially by encouraging ethically guided (not ethnically, as often misread) mate choice (1940, 1943). Starting in the mid-1950s, Lorenz's proposal of an evolutionary basis of human morals were attacked for various reasons or dismissed as unfounded. As competing hypotheses – especially those claiming sole environmental control of ethical behavior – have failed so far to resist falsification, these issues are, on the scientific level, far from resolved.

Lorenz's concern about human evolution running awry and leading us to extinction by our destruction of the environment was not merely a consequence of the atrocities of World War I, World War II, and of the nuclear demise scenarios of the Cold War, but had been deeply rooted in both his trust in science and in his allegiance to the Hippocratic oath. Thus, when by the vagaries of political and economic interests a nuclear power plant was built near his home in Altenberg, at a location that had been flawed by previously undisclosed risks, he opposed completion of its construction violently. Soon he found himself the revered leader in this fight that ultimately prevented the key-ready nuclear power plant from going into service. A few years later, Lorenz was equally successful in a fight to save the last stretch of wetlands along the Danube.

Relevance

Lorenz's impact on behavioral and social science is linked closely to his collaboration and friendship with Niko Tinbergen, and it is difficult to measure each one's individual contribution. Both were curious naturalists endowed with outstanding skills

in observing, in detecting regularities – patterns of nature – and in formulating testable hypotheses; and, both were outstanding teachers (e.g., Lorenz, 1949, 1950c). While Tinbergen was more inclined toward an experimental approach, as exemplified in their joint paper (Lorenz and Tinbergen, 1938), Lorenz's imprint on ethology is obvious in matters of pure observation, inductive reasoning, and formulating a comprehensive theory of the modular concept of action patterns and releasing mechanisms, of these modules being shaped by evolution as well as by learning, and of imprinting as a special type of learning.

A first attempt to estimate Lorenz's impact on his field from citation frequencies (Leydesdorff, 2001) indicates an increase of citation frequencies well above the current average.

Selected Topics

Lorenz achieved his scientific breakthrough in 1936. At an invited lecture before the German scientific elite of the Kaiser-Wilhelm-Gesellschaft in Berlin, he proposed to stop arguing about how many drives and instincts one can define, and instead start describing and analyzing behavior patterns as though they were anatomical features. In a discussion following the lecture, Max Hartmann, doyen of German biology, remarked that "Konrad Lorenz's approach opens up to causal analysis a field that was previously just a playground for fruitless philosophical speculation" (Lorenz, 1992).

World War II severely restricted research and exchange. However, soon after the war had ended, Tinbergen traveled in the UK and the United States presenting the new, ethological approach to behavioral studies, his effort culminating in his book *The Study on Instinct* (1951). Lorenz, who, up to then, had established an international reputation only among ornithologists, argued the case for a biological approach to the study of behavior and soon became the leading theoretician in the new science of ethology.

The high esteem for ethological research resulted in generous support by the Max-Planck-Gesellschaft, and subsequently by various national funding agencies, notably National Institutes of Health in the United States. Small informal meetings soon turned into international affairs. The biennial *International Ethological Conferences*, dominated by the Lorenz–Tinbergen School and 'converts' from a variety of related fields, became the central event for discussing new results and theories. The German journal *Zeitschrift für Tierpsychologie*, founded in 1937 with Lorenz as one of its editors, the first journal to favor ethological publications, soon got an English language companion in the Dutch journal *Behaviour*. As publications in the new science steadily increased *Animal Behaviour* was introduced a few years later as the official organ of Animal Behavio(u)r Societies that were founded in the United States and UK. While *animal psychology* and *comparative psychology* had been little-known specialties, dealing mainly with the learning abilities of rats, the Lorenz–Tinbergen-inspired new *animal behavior* became a hot topic for lectures in academic departments both in biology and psychology, resulting in a demand for teachers and textbooks (e.g., Eibl-Eibesfeldt, 1997, 1999), and spawning new opportunities and funding for behavioral research.

Since Lorenz, Tinbergen, and their colleagues were not only qualified biologists, but are also equally well established in neighboring fields, the popularity of ethology soon led to fruitful cooperation, notably with sensory physiology, brain sciences, and psychiatry (e.g., Lorenz, 1953). This process had considerable impact on the emergence of neurobiology, psychobiology, and evolutionary psychiatry, emphasizing a naturalistic, Darwinian approach at a time when the general trend in biology was toward molecular biology and biochemistry.

Subjects of ethological research at first were mainly vertebrates – birds, mammals, and fishes – and insects. The new approach was tested successfully and applied to all kinds of species, including our own. Even though the magnitude and difficulties of a task like establishing a human ethogram may appear mind-boggling, 'human ethology' becomes workable as a special case of primate ethology (e.g., Eibl-Eibesfeldt, 1997). A healthy human newborn faces similar tasks as any other primate baby and behaves very similarly.

By applying ethological methods within the framework of natural science and evolutionary reasoning, similarities and differences between human and nonhuman animals are no longer a matter of poetic license, but causal analysis – not, however, without drawing heavy critique from the old religious and political establishment. *On Aggression* and *The Waning of Humaneness* (Lorenz, 1963, 1983) are examples of an ethological approach to the moral strongholds of the humanities.

Human ethology has become a domain of its own, of broad overlap not only with primatology, but also anthropology (physical and cultural), psychology, and sociology, leading toward a new synthesis of knowledge, which proves that the old distinction between hard sciences and humanities has become obsolete.

Politics

Fame has its price. Especially since having been awarded the Nobel Prize, Lorenz has been branded a racist and an anti-Semite and alleged to have provided a pseudoscientific justification for the Holocaust (e.g., Klopfer, 1999).

In regard to these allegations, we must consider first that Lorenz grew up within a part of the Viennese society that was enmeshed intimately by friendship, marriage, and professional ties with the wealthy Jewish elite. He maintained these connections throughout his life by hosting many guests and being a guest on many in his frequent travels of old and new friends especially in England and the United States, and was certainly more pro-Semitic than average, and far less racist, especially than some of those who are now raising their voice. Thus, the charge that he advocated racist and anti-Semitic genocide is unfounded.

With respect to the allegation that Lorenz provided a pseudoscientific justification for the Holocaust, it must be considered that there is a long chain of inferences necessary to connect his controversial writings on the potentially dangerous effects of human self-domestication on the biological basis of ethical (not, and never ethnical!) behavior, or Lorenz's proposed use of eugenics to combat the rise of unethical behavior, to the atrocities of the Third Reich. And, there is no indication – in spite of many inquiries and searches (summarized in Klopfer, 1999) that prior to the end of World War II anybody in power was aware of such a link. Lorenz being called to the army early in World War

II, his first assignment as a rifleman and later as medical NCO (never promoted to a higher rank) gives ample evidence that he lacked political pull (Schleidt, 2000, 2003).

Lorenz became active in politics only after his retirement. As a Nobel Laureate, he was 'welcomed home' by the Austrian socialist elite. Given all the academic and public honors he had received, people listened when he spoke – as he proudly proclaimed – and he spoke loudly and clearly for environmental preservation and moral responsibility. He became the figure head of the growing 'Green' movement, both in a referendum against the use of nuclear power (5 November 1978) and in the "Konrad-Lorenz-Volksbegehren" (March 4–11, 1985) against the hydroelectric power plant in Hainburg that threatening the destruction of the surrounding wetland (Schleidt, 2000, 2003).

Concluding Remarks

Konrad Lorenz had been interested in a wide variety of animals, ranging from ciliates to primates, and among the fishes his special interest had been in Cichlids and the native cyprinids of Austria, however, most of his research had been focused on birds, notably corvids and waterfowl.

He established a breeding colony of Jackdaw in the attic of his home in Altenberg, and built there a pond for his ducks and geese. When in 1955, the dream of his life came true and he was allowed to choose – together with Erich von Holst – the site for their 'Max Planck Institute for Behavioral Physiology,' the banks of a little Bavarian lake, the 'Esssee' were picked for the location, as the most suitable place to study waterfowl in their natural environment.

When in the mid-1970s sociobiology made the headlines and behavioral ecology started riding the new wave of environmental awareness, the glamour of ethology began to fade. In 1999, the crown jewel of ethology, the Max Planck Institute at Seewiesen, was threatened to be closed, but offered a new lease on life as an ornithological research station. In 2004, this research unit was renamed and rebuilt as Max Planck Institute for Ornithology.

The ideas conceived and publicized by Lorenz, Tinbergen, and their contemporaries as the foundations of ethology have become public property. This may be the best indicator of the importance of the work of Konrad Lorenz, and of ethology.

Abstract

When A.J. Lotka died in 1949 his obituary in the *Journal of the American Statistical Association* began 'A brilliant chapter in modern demography came to a close with the death of Alfred James Lotka.' David Smith calls him 'the father of mathematical demography.' And these were understatements of his contribution, for demography was only a part of Lotka's scientific interests – he was also described as chemist, physicist, biologist, and actuary. What is common in all that he wrote was a search for better understanding through the use of mathematics. His name often appears in the literature as the author of the renewal equation – a mathematical expression of the mechanism by which the generations succeed one another – and as the codiscoverer of the Lotka–Volterra equations for predation and other interactions of multiple species in population biology. Of Lotka's many publications the two best known are the *Théorie analytique des associations biologiques* (1939) (translated by David Smith as *Analytical Theory of Biological Populations*) that provides the basis of modern mathematical demography, and *Elements of Physical Biology* (1925) that looks at the whole of the living world from a physico-chemical perspective.

When A.J. Lotka died on 5 December 1949 his obituary in the *Journal of the American Statistical Association* began 'A brilliant chapter in modern demography came to a close with the death of Alfred James Lotka.' David Smith, translator of his major work in the field (Lotka, 1939), calls him 'the father of mathematical demography.' And these were understatements of his contribution, for demography was only a part of Lotka's scientific interests – he was also described as chemist, physicist, biologist, and actuary, everywhere seeking better understanding through the use of mathematics.

Lotka was born on 2 March 1880 in Lemberg (Lvov), a Polish town of the Austro-Hungarian Empire, of American parents who were traveling Moravian missionaries; he died in Red Bank, New Jersey. His training was international: a boyhood mostly in France; a degree at the University of Birmingham (BSc 1901, DSc some 10 years later); graduate work in physics at Leipzig. Coming to the USA in 1902, he worked for the General Chemical Company, briefly for the US Patent Office as a patent examiner, and for the National Bureau of Standards as a physicist. He was editor of the *Scientific American Supplement* (1911–14), finally settling in the Statistical Bureau of the Metropolitan Life Insurance Company (1924–47). He was for long a bachelor, somewhat shy, described as quiet, learned, modest, and gently humorous. In 1935 he married Romola Beattie; they had no children. He was elected President of the Population Association of America (1938–39) and of the American Statistical Association (1942).

In his terminal year of graduate school, at Cornell in 1908–9, he began work with Professor F.R. Sharpe that led to the famous renewal equation – a mathematical description of the replacement of the generations:

$$B(t) = \int_{\alpha}^{\beta} B(t-a)p(a)m(a)da \qquad [1]$$

In the simplest case, rates of birth and death are constant over time, there is no migration to or from the defined area and the female sex only is considered. These conditions make possible a strict accounting of the relation between two generations. For on the right side is $B(t–a)$ the number of births a years earlier ($\alpha<a<\beta$ where α is the youngest age of childbearing and β the oldest); $p(a)$, the probability that a child born a years ago survives to time t; $m(a)$ is the birth rate for women aged a; integrating gives current births and so should be comparable to the births $B(t)$ on the left side. The unknown quantity that should make the two sides equal is the trajectory of births, to be provided in terms of the known functions $p(a)$ and $m(a)$. If the trajectory of $B(t)$ in Eqn [1] is simplified down to a curve of geometric increase, as Lotka initially assumed, then the question posed by the renewal equation is what rate of increase of births would equate the two sides of Eqn [1]. If that rate is r, taken either arbitrarily or from past data, then the age distribution of the population would stabilize over time to numbers proportional to $\exp(-ra)p(a)$ at the several ages a.

In finite intervals of time and age, Eqn [1] can be expressed naturally as a recurrent series and this was done by Lotka himself late in his career. P.H. Leslie formulated it in matrix terms. To these can be added a fourth version in partial differential equations (Keyfitz and Keyfitz, 1997), that also shows and compares the three other formulations.

Like most other discoveries, this one had predecessors who in part anticipated, as well as followers who marginally improved on, Lotka's work. Leonhard Euler (1760) came close on the theory; Edwin Cannan (1895) in the nineteeth century published an arithmetic calculation projecting the population of England and Wales that forecast the (then surprising) fall in births. R. Kuczynski (1931) and Richard Böckh of the Berlin Statistical Office were important predecessors working with the ratio of change per generation, the Net Reproduction Rate (NRR), $R_0 = \int p(a)m(a)da$. Willy Feller (1941), Princeton mathematician, noted that the solution to the renewal equation fell out simply and rigorously if each of the functions involved is translated into its unique Laplace Transform. Golubitsky et al. (1975) published an even more compact and more general solution.

Lotka went on to other demographic questions. He was curious to know why old populations have so few surnames and

[†]Deceased.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61079-6

found the answer in a pure probability accounting for the extinction of family lines (1931a). He ascertained the frequency of orphanhood as a function of birth and death rates (1931b) and calculated the money loss to dependents and to society when a person dies prematurely (Lotka and Dublin, 1946). In an early paper he went beyond human populations on the mode of growth of self-renewing aggregates; then on industrial replacement – for instance in a fleet of trucks of varied ages – he showed how the mathematics fits trucks as well as people.

Lotka's *Elements of Physical Biology* (1925), composed between 1922 and 1924 under a fellowship arranged by Raymond Pearl at Johns Hopkins University, is sharply distinguished from his earlier work – it looks at the whole of the living world from a physicochemical perspective. A first chapter on definition rejects a concept of life that sets it up behind an impassable boundary, such that living matter can never emerge through physical and chemical mechanisms. But it must have so emerged at least once in the history of the planet, and that emergence was of interest to Lotka.

Lotka anticipated modern ecology in his continual search for cyclical processes. One of many examples is the circulation of sulfur, that may be summarized from the *Elements of Physical Biology* as follows.

Sulfur occurs in abundance in inorganic nature in the form of the sulphates of the alkalies and the alkaline earths. Plants assimilate these compounds directly and then form proteins containing from 0.3 to 2% of sulfur. In this form it is assimilated by animals, who excrete the element chiefly in the form of sulfates. These, returned to the soil, complete the cycle.

And in the same way, Lotka portrays the cycles of water, iron, chlorine, and other components of the earth's crust. He took the science of these cycles from Swedish chemist Arrhenius and others, but he gets credit for being among the very first to see how crucial these cycles are to life and how they fit into and sometimes exacerbate one another. The number of people in the world more than doubled since his time, and production per person far more than doubled, so we are now forced to attend to such cycles as those of fresh water and carbon, and they enjoy considerable attention in legislative bodies and space in late twentieth-century newspapers and magazines. But all that is a development of the late twentieth century, so we have to remind ourselves that these issues were a preoccupation of Lotka from early in the century when there were very few far-sighted enough to think they might have practical consequences.

Lotka refers to the Swedish chemist Arrhenius who first saw from theoretical considerations the possibility of man-made carbon dioxide leading to global warming, and he cites Arrhenius' finding that the air is becoming richer in CO_2. Moreover plants, especially trees, withdraw CO_2, and the cutting of trees releases CO_2; the oceans could offset the tree-cutting by increasing their absorption of the gas. These are only three of the determinants of free CO_2 in the air and no one has yet shown a way to isolate the man-made CO_2 released by the burning of fossil fuels and cutting of forests from changes in the capacity of the oceans to hold carbon. Seventy-five years ago Lotka had a realistic view of the complexities of global equilibrium and the difficulties of forecasting what forces would dominate within it. The earth is a vast and complex physico-chemical-biological engine in constant motion, and if this is now a commonplace, Lotka was in the forefront of those who made it so.

The Lotka–Volterra equations are much referenced. Vito Volterra, an Italian mathematician, was asked by his biologist son-in-law Humberto D'Ancona whether he could explain the cycles of fish population in the Adriatic Sea. Lotka, also in the first half of the 1920s, wanted to see whether the relation of predator and prey could be assimilated to the autocatalytic processes of chemistry he had studied earlier. A pair that comes to mind as a model for both Lotka and Volterra are foxes ($F(t)$) and rabbits ($R(t)$), in which a carnivorous species is dependent on a grass-eating species. The flow of energy is *sun* → *grass* → *rabbits* → *foxes*. Lotka (1925) and Volterra (1927) seem independently to have noted and explained the same features of predation, especially the cycles it generates. The simplest form of the Lotka–Volterra equations is

$$F'(t) = -\alpha F(t) + \gamma R(t) \qquad [2]$$

$$R'(t) = \beta R(t) - \delta F(t) \qquad [3]$$

Primed symbols are derivatives, and the four positive numbers α, β, γ, δ are fixed parameters. The $-\alpha$ in the first equation tells us that in the absence of the prey (i.e., if $R(t)$ is zero) then the predator declines in numbers, to ultimate extinction. The second equation shows the prey increasing indefinitely in the absence of the predator. That γ has a plus sign in the first equation allows for the fact that with more abundant prey the predator grows faster. With other configurations of signs the same equations can represent competition, symbiosis, etc. They can incorporate limits on the amount of grass and can be extended to three or more species.

Lotka's indifference to what he considered mathematical niceties was matched by a quality found in many other original minds, great sensitivity on priorities. He engaged in a long and indecisive controversy with R.R. Kuczynski. The history of science is pockmarked with such disputes. What puts this one in a special class is that Paul Samuelson undertook a uniquely thorough investigation (1977) to sort out the issues, and credits Lotka, Böckh, and Kuczynski, among others. With access to the Princeton archives where Lotka's private papers, as well as his publications, are deposited, he demonstrates with the help of pages of solid algebra that Lotka's predecessors turned up a good part of the renewal story, but their work was incomplete. Lotka had both the theoretical interest and the command of data, plus the drive to follow through.

So, Samuelson concludes on this issue, the brighter light has drowned out the earlier light. But now that the dust has died down, it looks as though Lotka's place in history, which is a secure one, is based less on the priorities he claimed so vigorously in controversy than on his anticipation and objective treatment of a complex of problems revolving around population and environment, problems barely suspected when he lived, that we now realize will be with us for a long time. A half-century after his death he is very much alive through his books and papers, and in the demographic profession we can still say, with Frank Notestein (*see* Notestein, Frank Wallace (1902–83)), that 'his is the greatest name.'

Abstract

Intimacy occurs when two people are responsive to each other, self-disclose, and demonstrate involvement behaviors. This interactive process may culminate in love and the establishment of a close relationship. Love is the evolutionary result of innate bonding and mating systems such as attachment, caregiving, and sex. It is a variable experience taking the form of attachment, compassionate, companionate, or romantic love. Love styles are relational attitudes about love. Love types result from combining intimacy, passion, and commitment. Love stories explain the social origin of love's meaning and change. Companionate love features are prominent in laypersons' love prototypes.

If close relationships form the foundation and theme of the human condition, love and intimacy represent the invisible master plan that humans apply in building their close relationships throughout their lifetimes. The two concepts are often closely associated in popular and scientific discourse as they capture core phenomenological experiences and processes involved in the initiation, development, and maintenance of relationships. They both reflect the universal and biologically ingrained human need to create and maintain dyadic attachments, affiliations, and networks of interdependence which secure that a cohesive and self-perpetuating community supports and maximizes individual well-being. At the individual level, love and intimacy directly or indirectly affect personal well-being; self-worth; and the motivation for self-expansion, social-adjustment, and community connectedness. At the close relationship level, they affect both relationship stability and longevity, perceptions or relationship quality, satisfaction, expectations about the relationship, and the motivation of maintaining it (Berscheid and Regan, 2005).

Intimacy has for the most part been viewed as a dynamic interactive process between two people that enhances their motivation to keep engaging in behaviors that may gradually increase knowledge of each other, mutual understanding, and bonding. In contrast, love has been studied as a phenomenological cognitive–affective state, resulting from a broad range of processes including intimacy. In our discussion of intimacy, we will first analyze the specific qualitative characteristics of the behavioral patterns that people elicit in interpersonal contacts. Subsequently, we will describe a model that attempts to explain by means of what process, the interacting behavioral patterns elicited by the dyad involved in the interpersonal contact, generate, maintain, and augment intimacy.

Intimacy as a Relationship Process

Intimacy may well refer to a transient experience of sharing private personal information with another fellow human being, such as an unknown fellow traveler, sitting next to us, on a long transatlantic flight. However, it usually refers to entire patterns of verbal and nonverbal behaviors occurring at the onset or within a relationship, which bear characteristics consistently reflecting motivation for (1) self-disclosure, (2) self-involvement, and (3) responsiveness, that is for seeking signs of interest and involvement on behalf of the other person (Laurenceau et al., 2004a,b; Prager, 2000; Prager and Roberts, 2004; Reis et al., 2004).

Self-Disclosure

Self-disclosure may include revealing objective private information about the self as well as expressing motives, needs, wants, goals, fears, and feelings in general (Laurenceau et al., 2004a,b). For instance, individuals may talk about their personal history, relationships with family members, important career milestones, people who have influenced their lives, past positive and negative/traumatic experiences, past failed relationships, sadness, risks, hurt, pain, emotional nakedness, feelings of being a special person, superior or inferior to others, privileged or flawed, and so on. At the initiation of a close relationship, the objective of self-disclosure behaviors is to establish (1) the subjective perception of a virtual safety zone between the two interacting individuals, so that the more vulnerable aspects of the self can be communicated and exposed without the apparent risk of getting hurt, (2) to make self fully known to other for what it is, for its brighter and darker sides, and (3) to seek understanding and acceptance and ultimately claim unconditional positive regard for what the self is as a whole. To the extent that these objectives have been attained, intimacy's role shifts to transforming each relationship member's perception of his/her individual outcome interdependence in the relationship. The interdependent partners acquire a 'we' perspective and by perceiving relationship outcomes as own, they tend to pursue maximization of joint gain. Intimacy transforms the relationship into a union of trust (Kelley, 1983/2002; Rusbult et al., 2004).

Involvement Behaviors

Involvement behaviors are, for the most part, nonverbal and convey attentiveness, interest, and active participation in the interaction with other (Prager, 2000). People may thus actively seek eye contact and gaze at each other for an extended time, may sit closer to one another, assume open posture, lean

forward, gesture, smile or in other ways show facial animation, and nod their heads while listening and talking. As interactions among the intimate couple unfold and multiply, touch is among the behaviors that may further intensify the intimacy experience. Invited touch of parts of the body that have been identified as vulnerable, such as the face or the torso is very likely to yield strong feelings of intimacy. These feelings are intensified when individuals sustain the touch, as in the case of embracing other or when placing arms around the shoulder or the waist. When the interaction between two individuals has ensued from initial sexual attraction, or intimacy has brought about sexual attraction, sexual contacts and sexual intercourse among the couple can escalate behaviors of intimacy and the breadth and depth of the experienced intimacy. However, sexual touch or sexual expressions do not necessarily bring about intimacy. When interacting parties have the subjective feeling that the 'safety zone,' mentioned above, protecting the more vulnerable aspects of self from exposure, is not in place, sexual advances or any involvement behavior may irreversibly hamper intimacy or destroy the relationship per se.

Involvement may also be expressed by means of verbal behavior that conveys either the message of desired proximity or simply positive affect for being close. The functional objective of involvement behaviors in establishing intimacy is to demonstrate behavioral intention for approaching and getting involved with other and to test other's responsiveness and behavioral intention for approaching self. In developing and maintaining a relationship, involvement behaviors mainly function to maintain immediacy of emotional reward among the couple and support mutual interdependence with positive affect and management of negative affect.

When people are motivated to initiate and maintain intimate relationships, they increase the frequency of involvement behaviors, actively employ a broad range of modes of communicating (phone, texting, e-mailing, social media, etc.), and subjectively 'make time' to engage in interactions.

Responsiveness

Responsiveness refers to the active and focused attention, the discerning perception, and the timely and sensitive response to what is being said and done by other during an intimate interaction (Prager, 2000; Reis et al., 2004). Responsiveness in intimate interactions requires that the nature of disclosure and involvement behaviors emitted by other, first be identified for what they are, second be discerned for the specific intention or content expressed, and third be addressed in one way or another or ignored.

Responsiveness behaviors may be both verbal and nonverbal and their function is to denote that the disclosing person is followed and understood with attention and empathy. In particular, nonverbal behaviors play a substantial role in people's experience of intimacy perhaps due to their immediate association with affective reactions and the fact that they are, at least, partially involuntary. Such behaviors may include attentive listening, head nodding, eye contact and gazing, variation of voice tones, facial expressions, smiles, gestures and body postures such as leaning forward or assuming an open posture. Occasional bodily contact, such as hugging and touching other in a heartening and reassuring manner during critical disclosing moments, may also occur. Although such behaviors superficially resemble behaviors of involvement, they are essentially different because their function is to facilitate disclosure (e.g., by establishing appropriate physical distance) and other's voluntary choice for testing engagement in involvement behaviors. Short and extensive or elaborate verbal responses in intimate interactions also function to communicate that the listener is interested in what is being said and willing to listen further and invest time in the interaction. Moreover, they can overtly convey understanding, acceptance, respect, and genuine care.

Partners of a close relationship recognize each other's responsiveness by using four procedural criteria: (1) How often other responds to one's communicative behaviors and how predictable are their responses. High frequency indicates high responsiveness, whereas predictability creates a sense of familiarity and warmth, as other seems to 'always' understand own behavior; (2) How many of own behaviors are responded to by other appropriately, that is taking into consideration their exact content (obviously, the statement 'I am desperate' cannot be responded with 'shall we have something to eat?'); (3) How many of the responses are suitably elaborate; in some interactions initially responding 'I understand' or 'I know' to 'I am sad' may be fitting, whereas in others a more extended answer would have been more welcome; and (4) How timely are the responses; timely response suggests reassuring predictability of other's behavior toward self, which in turn implies controllability. If these criteria are met, relationship partners feel that other values the relationship and their interaction, otherwise partners feel frustrated and the relationship may lead to dissolution.

Disclosure, involvement, and responsiveness behavioral patterns do not function independently, but are sensitive and proactive/reactive to the onset of each other, the timing and the source of expression. Actually, intimacy seems to result from a highly interactive, recurrent cybernetic loop among the behavioral patterns elicited by the two communicating individuals. Thus, the dyadic generation of intimacy needs to be effectively depicted by a process model. Below, we roughly outline such a model based on the influential interpersonal model of intimacy that has been proposed by Reis and Shaver (1988), Laurenceau et al. (2004b).

A Dyadic Intimacy Process Model: Disclosure, Involvement, and Responsiveness at Work

The model describes intimacy as an interpersonal interaction between A and B that goes through a preconditional proactive–reactive stage (I), a mediating perceptive stage (II), and an outcome stage (III). The latter stage may feed back into stage I, regulating the continuation of the intimacy interaction cycle, the shifting of the proactive or reactive roles (e.g., disclosing vs listening), its climaxing or anticlimaxing, and/or eventual stop:

I. This stage starts off with proactive self-disclosure behaviors on the part of A. It may be a piece of private information or a feeling or both e.g., 'I am so sad…' or 'I am so sad, I just broke up with my relationship.' It continues with reactive or responsive behaviors on the part of B. They could

be a verbal response timely expressed, e.g., 'Why? What happened?' accompanied by an eye contact showing sympathy. B may also sit closer, showing readiness to listen and encourage A to talk about his or her feelings. While listening, B may follow A by maintaining eye contact, head nodding, and using facial expressions to demonstrate understanding, sympathy, and support. On the other hand, B's responsive behaviors may denigrate or 'invalidate' the feeling expressed or show disinterest and change the subject, e.g., by saying 'Oh, breaking up is always sad for everyone! Are you going to watch the Oscars tonight?'

II. If A perceives B's responsive behaviors as demonstrating that (1) she is being followed and understood for what she says, (2) she is validated, that is the significance of the contents of self-disclosure is recognized for what it is and the discloser is respected for her experiences and feelings, (3) she is cared for, as a person, that is B seems to be to a greater or lesser extent emotionally involved with her, then stage III, the outcome stage is activated.

III. A perceives B's reactions as a positive outcome of the interaction and a sign that more proactive intimacy behaviors may be rewardingly tried out by him or her (that is, by A). At the same time, such reactions work as a predictive sign that similar proactive behaviors are to be expected from the other party (B). In this case, the process is repeated across time and even across different settings with A and B exchanging roles (proactive vs reactive). The feedback loop (I–III) may climax with even more intense and diverse self-disclosure, responsiveness, and involvement behaviors.

When the recurrent functioning of the intimacy model's feedback loop, and the spiraling exchange of disclosure, responsiveness, and involvement behaviors is mutually rewarding, the intimacy process may be sustained for a long period of time, across multiple and diverse interactions. Eventually, the interacting parties start exerting strong, frequent, and diverse effects on one another (Kelley, 1983/2002), establishing a close or 'intimate' relationship.

Love

Love can better be understood as the subjective perception of an affective–cognitive state that may have resulted from dyadic intimacy as well as any of several relationship processes occurring in multiple dyadic, community, or other contexts, ranging from the romantic relationships, family relationships, one's fellow human beings, or even one's relationship with God (Berscheid and Regan, 2005). Indeed, love is a broad, multifaceted concept and although it is relatively easy to self-report when experienced, it is nearly impossible to define in abstract terms, without reference to its specific characteristics and the relationship settings in which it occurs (Kelley, 1983/2002).

In our discussion of love, we will first present the biopsychological perspective, which views love as the by-product of two biological processes that have assisted humans in successfully responding to the evolutionary challenges of social living and reproduction; one refers to the human bonding, the other to mate selection. Then, we will present the taxonomies of love, that is theorizing about the contextual variations in the meaning of love from both a scientific and a lay perspective.

The Biopsychological Perspective

Shaver et al. (1988) in their highly influential theory on romantic love, based in part on Bowlby's (1979) ethological theory of attachment, suggest that there are three innate motivational systems: attachment, caregiving, and sex. All three have evolved over the course of human development to increase the likelihood that the vulnerable human infant, which requires nurturing support for an extended period of time, will survive and reach a reproductive age. Each system has different aims and dictates different strategies in achieving these aims. The aim of the attachment system is to help the person establish a psychological bond with an attachment figure, so that he or she can seek shelter when coming across a threat and feel that relationships, in general, can be more or less predictable and trustworthy. The caregiving system yields protection and support for significant others in need. The sexual system secures that sexual partners approach and focus on each other at the expense of other activities or others with the aim of reproduction. Each of the three motivational systems may receive different feedback from the infant's or child's caregiver (usually the mother) and his or her significant others. In turn, the infant or child, based on this feedback, establishes behavioral strategies or patterns of probabilistic responses to relational stimuli that guide his or her relating behavior later, in adult life, including mating and romantic relationship behavior.

Research (Shaver and Mikulincer, 2006, 2011) has examined individual differences in attachment strategies (secure, avoidant, and anxious) and their association to the other two systems. More specifically, securely attached people are more likely than nonsecurely attached ones to provide effective care to a needy partner as they have a stringer sense of efficacy and controllability in coping with distress. They also tend to be more responsive and caring. In contrast, avoidant people are less willing to be compassionate to others and provide care. Anxiously attached people are preoccupied with their own needs and are thus unable to react to others' suffering with empathy. In contrast, they react with own distress which hampers their ability to provide effective, sensitive, and unintrusive care. In terms of sexual expression, anxiously attached people seek to maintain their own protection and security and would have trouble attending to their partner's sexual needs and preferences. They tend to use sex to reassure themselves and cast off their fear of abandonment. Avoidants may feel uneasy during sexual intercourse that requires even the minimum of intimacy, as they dislike exposure to vulnerability and openness; they tend to dismiss care and avoid intimacy often involved in sexual intercourse. Avoidant people may also be using sex instrumentally, as a way of manipulating others in pursuing ulterior goals.

Fisher's (2006) neurological approach also proposes three different brain-based systems: the sex drive, attachment, and attraction. Sexual desire springs out of the sex drive system, and aims at successful reproduction. Attachment refers to nest building, the establishment of proximity with other, and mutual

caregiving. Attraction describes investing energy and time at focusing on one particular mate and on mate-guarding. Fisher's sex drive and attachment systems resemble Shaver's sexuality and attachment systems, respectively. However, Fisher's definition of 'attraction' is more clearly associated with passionate and romantic love. By contrast, Shaver's conceptualization of the caregiving system is more related to compassionate or companionate love. All three kinds of love will be discussed in the taxonomies of love section.

The functioning of the systems proposed above seems to be supported by biobehavioral mechanisms, common in mammals, including humans (Leckman et al., 2006). For instance, the contention of attachment system (Shaver's) and attraction systems that falling in love is stressful and may thus require anxiety regulation is in consonance with the finding of increased cortisol levels among passionate lovers. On the other hand, peptides, such as oxytocin, have been found to reduce and relax the anxiety involved in both passionate love attachment and other forms of bonding. Low serotonin levels seem to be responsible for anxious obsessive behaviors often observed in people in love.

The evolutionary approach to love (Kenrick, 2006) states that different kinds of love are relevant to different problems humans have encountered during their evolution. For instance, humans need to attract potential mates; once they do so, they have to maintain a relationship with them for a significant time period so that their offspring is taken care off in the best possible way. In responding to this problem, males, generally, have acquired the bias to ascribe more importance to attractiveness in females, because attractiveness serves as a cue to fertility. In contrast, females, in selecting and, more particularly, in maintaining a mate pay attention to his status, that is to his ability to provide for the offspring. Thus evolutionary problems such as mate-seeking and parental care, that require different solutions, may have dictated the development of different kinds of love. The former may be subjectively perceived as being primarily focused on sexuality and passion, whereas the latter on caregiving and attachment.

Love Taxonomies

Taxonomies of love are the result of systematic efforts to organize the multiplicity of phenomena described under the use of the word 'love' in the broad array of social contexts it usually occurs. Love taxonomies are useful not only because they facilitate us in describing similar observable phenomena associated with each kind of love, but also because they help us understand the causes of such phenomena and predict their future course (Kelley, 1983/2002).

The Quadrumvirate of Love

Ellen Berscheid (2006) has suggested that the already discussed attachment love and three more kinds of love can cover all love-associated phenomena. Thus, below we turn to the discussion of compassionate, companionate, and romantic love.

Compassionate love motivates altruistic interest for another's welfare as well as actions to promote it (see also Fehr and Sprecher, 2009; Sprecher and Fehr, 2005). It has also been labeled 'altruistic,' 'charitable,' 'brotherly,' 'communal' love, 'agape,' and 'B-love'; behaviors associated with it have also been studied under different names, such as 'prosocial behavior,' 'caregiving,' 'support behaviors,' and 'communal responsiveness' (Clark and Monin, 2006). Individuals engaging in compassionate love do not expect that their actions will be reciprocated. Compassionate love is based on the caregiving system described in the context of Attachment Theory. Humans are born weak and vulnerable, and in order to survive and reach reproductive age, they need the 'asymmetrical' support of an older, stronger, and wiser member of their species. The survival utility of this asymmetry has been inherited to our species members over evolutionary time. Compassionate love involves responsiveness to clear or discreet signs of need, sensitivity in understanding the nature of the need, and unobtrusive behaviors to alleviate it.

In contrast to compassionate love, companionate love (see also Hatfield, 1991) is contingent upon rewards and punishments. The evolutionary and survival value of the pain–pleasure principle, basic to learning and behavioral theories, underlies this kind of love. People love those who love them back, or more precisely those who reward them. Companionate love has been discussed in the past under terms such as 'liking,' 'friendship love,' 'philias,' 'affiliation,' 'pragmatic love,' and 'affection.' Companionate love relationships are often based on characteristics that are intrinsically rewarding to both relationship partners such as physical attractiveness; familiarity; similarities in background, goals, and values; and common interests. Companionate love relationships are characterized by physical or virtual proximity, stability, positive feelings, mutually predictable and responsive behaviors, mutual recognition and acceptance, and the exchange of actual rewards. Intimate couples who experience companionate love feel that their lives are deeply interdependent; they see, understand, and accept each other for what they really are and tend to be best friends. Finally, they show mutual affection and concern for each other's welfare, have positive feelings for their partner, and tend to prioritize his or her needs against those of third parties.

Romantic love has been studied under names such as 'passionate,' 'erotic,' and 'addictive' love (see also Hatfield, 1991; Hatfield et al., 2007). It rises out of sexual desire and is based, to a large extent, on the neurochemical mechanisms we have previously discussed. Of course, romantic love is hardly limited to sexual desire. In attempting to capture its rich phenomenology, one has to unveil its cognitive, affective, and behavioral components. Cognitions reflecting romantic love include idealization of partner and the relationship, intrusive and often obsessive thinking about them, and a strong desire to know them and be known (self-disclosure). Emotions of romantic love comprise attraction, sexual attraction in particular, intense and conflicting feelings, elation and bliss, anguish and disappointment, as well as longing for reciprocity. Behaviors indicating romantic love include 'studying' the other person, trying to 'read' and determine their feelings, providing service to them, and maintaining physical closeness. Further, individuals in love tend to behave toward their loved ones according to their imaginary expectations about them, rather than according to realistic appraisals (Snyder et al., 1977; Berscheid and Regan, 2005). At the same time, as the basis of relating is fleeting and volatile emotionality, the ensuing relationship tends to be unstable, unpredictable, and sometimes unrealistic. Lovers do not see each

other as actual persons with real needs, but as projections of how they would like them to be (Hendrick and Hendrick, 2000; Berscheid and Regan, 2005).

As passion also tends to quickly deplete the organism's resources, romantic love withers away and cannot support the relationship for long. For this reason, relationships solely based on romantic love do not fare well in the long run. In the best case scenario, as romantic love grows weaker, companionate love, enhanced by intimacy built up, may gradually replace it, stabilizing the relationship and placing it on a more realistic basis. Romantic and companionate love, are not mutually exclusive; both kinds seem to be present at the initiation of a relationship and may function in a complementary rather than competitive fashion. In fact, most couples report that their lover is also their best friend (Hendrick and Hendrick, 2000; Berscheid and Regan, 2005).

Love styles

Love styles are ideologies of love or belief–attitude systems about how one loves other; they may not be necessarily subjectively perceived or consciously stated as such, but they are certainly expressed in interactions with others in intimate settings (Hendrick and Hendrick, 2006). In that sense, they can be construed as interpersonal cognitions about loving others that loosely dictate romantic social behavior. Thus, love styles are constructs comprising beliefs and attitudes about loving, relational personality traits, and a variable emotional core, reflecting the general need for affiliation. There are six dominant love styles: Eros (passionate, erotic, or romantic love), Ludus (game-playing uncommitted love), Storge (friendship or companionate love), Pragma (practical, calculating, and instrumental love), mania (possessive, obsessional, or dependent love), and Agape (altruistic or compassionate love). Plenty of studies have addressed research questions on the association between love styles and demographic, personality factors, and relationship outcome variables (e.g., satisfaction, sexuality, adjustment, quality, stability, longevity) (Hendrick and Hendrick, 2006; Neto, 2012).

The Duplex Theory of Love: The Triangular Theory of Love and the Theory of Love as a Story

The *Triangular Theory of Love* defines the concept of love structurally, in terms of its components. By understanding the functions and interrelationships of love components, Sternberg (2006) attempts to grasp the variations in the meaning of love, as well as the variability in behaviors associated with it.

The Triangular Theory of Love

According to the Triangular Theory of Love (2004), there are three components of love that can be metaphorically viewed as the three vertices of triangle. These are intimacy, passion, and decision/commitment and can be identified in various forms in older theories; moreover, they are intuitively meaningful to laypersons (Aron and Westbay, 1996). The component of intimacy comprises the phenomenological outcomes of the intimacy process that we have previously discussed. These are feelings of closeness, warmth and bonding, communication, understanding, caring, compassion, and empathy. Similarly, the passion component includes feelings familiar from our description of romantic love, such as sexual arousal and intense desire, longing for other's presence, obsession with the loved one, excitement, energy, enthusiasm, a sense that attraction is inevitable, and that attachment to other was destined. The decision/commitment component, in the short term, refers to the realization and decision that one loves other and is interested to enter and tentatively remain in a relationship. In the long term, it is the decision to be committed in maintaining it. Sternberg further proposes that the three components can be combined in eight possible limiting cases where the amount or proportion of each component is, for reasons of illustration, estimated to the maximum (or is fully present) and to the minimum (or is entirely absent). Thus, (1) absence of all the three components is nonlove, (2) intimacy alone is what we experience as liking, (3) passion alone is nothing but infatuation, (4) commitment by itself is empty love, (5) intimacy combined with passion without commitment is romantic love, (6) intimacy combined with commitment without passion is companionate love, (7) passion plus commitment without intimacy is fatuous love, and (8) intimacy combined with both passion and commitment is consummate or complete love. On an individual basis, all three components are strongly associated with happiness and satisfaction in relationships. Couples, however, tend to be happier to the extent that the balance among intimacy, passion, and commitment each of them desires approximates that of the other. For example, a couple may experience distress, if one of them wants a lot of passion but not much commitment and the other wants a lot of commitment while has no motivation to engage in full passion or wishes to withhold passion.

Structural analysis cannot inform us on the social origin and importance of love components, nor does it account about the dynamic change of love component combinations within a relationship. The theory of *Love as a Story* (Sternberg, 1995, 2006) explains where the meaning of love components comes from and how component contents and combinations may change over time in one's own relationship or across relationships.

The Theory of Love as a Story

Love Stories are guiding metaphors similar to cognitive schemata or scenarios that help people predict and possibly control the behavior of other and self within an intimate relationship. Stories come from our experiences with narratives, tales, books, TV series and movies, and observation of the relationships of our parents, our friends' parents, and our own. Stories have protagonists and require the casting of the 'supporting role,' that is of a partner who can fit the scenario and will accept to play the role. Some are willing to do so, some will not, and ask for the scenario to be edited or even changed. Compatibility or complementarity between the two basic roles and compatibility between role and scenario are of critical importance for relationship satisfaction and other relationship outcomes. Individuals differ in their flexibility to negotiate and edit or even change their preferred relationship love story. Our stories evolve and may change over time. However, we carry a hierarchy of preferred love stories and we are happier when we succeed in inviting someone to 'play' in our most preferred one. In contrast, if we eventually concede to participate in a story that is not high in our hierarchy, that relationship will probably yield less satisfaction for us and we are more likely to abandon it for a story higher in our hierarchy.

Research has identified a variety of about 26 common stories (Sternberg, 1995, 2006). Examples are (1) the fairy tale story, in which the protagonist is a prince or a princess, they expect that special other and live happily ever after, (2) the business story, according to which a relationship is run like a business with gains and losses, partners can make practical agreements and plans, (3) the travel story, in which partners travel together, along the same path, to a common destination, (4) the police story, in which one partner (the policeman) sets the rules and is always vigilant that other observes them, (5) the horror story, in which one partner abuses the other, (6) the collector story, according to which one partner collects lovers and admires them as showcase of precious objects. Research has shown that some stories are more adaptive than others (e.g., the travel and the fairy tale story vs the horror or the police story) as they help the individual adjust better to the relationship, while the relationship per se yields better outcomes. Couples have also been found to be more satisfied when their story hierarchies match.

The Prototype Approach

Seeking a breakthrough to the difficulties associated with defining love, Fehr (1994, 2006) resorted to people themselves and their own understanding of the love concept. The love prototype is based on spontaneously elicited features of love as well as on measuring how important these features are to laypersons in cognitively representing the concept. Prototype research found that companionate love features were clearly predominant in the lay perception of love. For example, features consistently found include trust, caring, honesty, friendship, and respect. Even when features were listed explicitly for romantic love, trust, honesty, and happiness ranked well above passion and sexuality. On the other hand, the same line of research has revealed that the romantic–companionate love distinction is meaningful and valid to laypersons.

Conclusion

Intimacy is the subtle process that brings to bear love, although potent feelings of romantic or passionate love may be initiated before even the timid steps of intimacy development have been taken. Indeed, romantic love only needs sexual desire, realism enough to focus on the desirable aspects of other, and a lot of imagination to augment them while disregarding undesirable aspects. Its evolutionary role is to lure the couple into the deceptive magic of love, away from daily concerns and other interests. Nevertheless, it is intimacy that will enhance the climaxing of romantic love and the one that will secure basic relationship functioning when passion inevitably subsides; intimacy will prepare the rise of companionate love that may eventually support the continuation and longevity of the close relationship.

Love, of course, is not limited to close relationships and thus intimacy is not important only for the romantic couple. Being sensitive and responsive to others, as intimacy suggests, is the basis upon which compassionate love thrives. Being 'asymmetrically' responsive to the need of others, without expecting reciprocation, has obviously been an evolutionary advantage for the survival of our species, because all people, irrespective of gender and age, will find themselves at one time or another in times of need. Attachment theory is keen on the notions of responsiveness, unconditional love, and caregiving. The mother, in the mother–infant archetypical asymmetric relationship can set with her responsive behavior, the basic precondition for the child to develop as an adult, a personal sense of autonomy, and the perception that his or her social world is predictable and trustworthy; he or she can love others and be loved without fearing separation, abandonment, and betrayal.

Love can also take on many forms and expressions. It is important to know what is intended behind each pattern of expression, love style, type of love, or love story. Although, romantic love during the peak of passion can take on a nearly irrational and obsessive character, loving settings allow partners to express their own perception of their relationship, listen to other's and negotiate upon it. Love styles, types, and stories can significantly contribute to our understanding of how we perceive the intimate relationship we are in, and what we expect from it and our partner. Individuals can alter their love stories if they feel that they have been trapped in the repetition of a destructive scenario and couples can mutually edit their love story until it becomes compatible and productive to both.

Abstract

Niklas Luhmann (1927–98) was a German sociologist who continued and renewed the tradition of sociological systems theory started by Talcott Parsons. Niklas Luhmann was impressive in adding new insights and concepts from phenomenology, medieval scholasticism, biology, cybernetics, social psychology, legal dogmatics, and other disciplines. Luhmann's theory is best characterized in comparing it to the major achievements of Talcott Parsons: An open, inductive list of global function systems supplants the deductive, binary logic of AGIL; 'World Society' supersedes the solidarity-based national communities postulated by Parsons; neo-Darwinist evolutionary theory pushes away the Parsonian thinking in developmental trends; communication takes the place of action, and generalized media of exchange become media of communication, which do not mediate exchanges between systems but bring about the core of autopoietically closed communication systems; a loose, hierarchical arrangement of interdisciplinary borrowings substitutes for the hierarchical conceptual structure of the Parsonian paradigm.

Biography

Niklas Luhmann was born on 8 December 1927, in Lüneburg (Hanover), as the son of a brewer; his mother came from the Bernese Oberland. Luhmann's family seems to have been permissive toward the children and distant from National Socialism. Luhmann attended a humanist Gymnasium at Lüneburg where he was an assiduous student. In spring 1943, Luhmann's whole class became helpers of the German flak at airports nearby. School hours continued irregularly at the location, and in autumn 1944, he had to leave school and become a regular soldier in South Germany. In spring 1945, the American army took him as a prisoner of war and transported him first to Ludwigshafen and then to a labor camp near Marseille.

As Luhmann still was not yet 18, he was released from the camp in autumn 1945. Since his secondary school degree was not accepted for academic study, he went back to Lüneburg and took a special class, which led to the 'Abitur.' He decided to study law, which was motivated by his supposition that law is the kind of knowledge system that can help with the breakdowns of order he had experienced. From 1946 to 1949, he was a law student at Freiburg with a strong interest in Roman law and in historical and comparative aspects of law. Luhmann went back to Lüneburg, became a trainee lawyer with a legal practitioner and prepared a legal dissertation, which was never finalized. He took his second state examination in 1953 and found his first job in 1954.

Having first worked with a private legal practitioner, Luhmann acquired a certain dislike toward dependence on clients. Therefore, he preferred public service and had his first job as a lawyer at a higher administrative court in Lüneburg (1954–55), then switching to the ministry of culture in the federal state Lower-Saxony in Hanover (1955–62). In these years, he slowly, through private study, became a sociologist. His first two papers were published in 1958 and 1960 in a journal for the sciences of administration. Then Luhmann applied for and received a stipend at the 'Littauer Center for Public Administration' (Harvard) where he studied primarily at the 'Department of Social Relations' with Talcott Parsons (1960–61).

Returning to Germany, Luhmann took a job at the research institute of the University for Public Administration at Speyer in 1962. In the same year, he published his classical essay on 'Function and Causality' in the 'Kölner Zeitschrift für Soziologie und Sozialpsychologie.' In 1964, Helmuth Schelsky, at this time probably the most influential German sociologist, asked him if he wanted to become a professor of sociology at the planned University of Bielefeld. Luhmann accepted and finished his 'Doctor of Philosophy' and his 'Habilitation' in 1966, taught in Münster and, in 1968, in Frankfurt (as a substitute for Theodor W. Adorno). Finally, in 1968, he was appointed as the first professor at the University of Bielefeld, 2 years before the first student inscriptions there. He stayed in Bielefeld until his retirement in 1993. Luhmann liked traveling, but otherwise he preferred a rather uneventful life of which he made use in producing the most impressive publication record of twentieth-century sociology. He lived near Bielefeld with his wife who died early (1977) and their three children. Only a few years after his retirement, Luhmann contracted a severe illness from which he died on 6 November 1998.

The Intellectual Development

We do not know much about early intellectual influences but a relevant circumstance is that Luhmann was a private scholar between the end of his law studies (1949) and his stipend at Harvard (1960–61). The intellectual education of Luhmann probably was much broader than usually is the case for young scientists who try to start a disciplinary career. From brief forays, we know about some of Luhmann's early readings: Camus, Dostoevsky, Hölderlin, Jean Paul, Thomas Mann; in these years, he had no reason to become a disciplinary specialist.

In reconstructing this intellectual education, there are two who had lasting significance for the genesis and structure of Niklas Luhmann's theories: Edmund Husserl (1859–1938) and Talcott Parsons (1902–79). Both of them, as soon as Luhmann got to know their writings, induced a cognitive shift via key

concepts deeply embedded in the structures of the theories Luhmann built. Luhmann, who did not give much weight in intellectual reconstructions to persons, made exceptions in his lectures for Husserl and Parsons. From this dual influence arose the synthesis of phenomenology and systems theory, which is historically unique: from Husserl, Luhmann took the strict separation of psychic systems (consciousness) and social systems (communication), which he radicalized in a way nobody had done before. He further adapted from Husserl the core mechanism used on both sides of the gulf between psychic and social systems: Meaning as a mode of selectivity, which builds complexity by remembering even those possibilities that were not chosen. Such a system built on meaning as its way of dealing with selections will incessantly oscillate between references toward its own states and references toward things external to it, a distinction that is akin to the Husserlian concept of intentionality.

From these examples, we can infer the originality of the strategy. On the one hand, the distinction psychic/social is radicalized, which implies a negation of intersubjectivity, as subjectivity is a concept suitable only for psychic systems. On the other hand – as meaning is used in social systems, too – the rich vocabulary of the European philosophy of consciousness becomes instructive for the understanding of mechanisms and structures of social systems.

The concept of social system is taken from Talcott Parsons and this process of taking stock of Parsons and reintegrating his conceptual structures into a completely reformulated systems theory is a still more important cognitive undertaking than the interdisciplinary discourse with Husserl. The logic in Luhmann's way of dealing with Parsons consists in making use of nearly everything Parsons invented, and in doing this to recontextualize every concept, a strategy that maximizes as well integrative continuity as it favors building completely new conceptual structures.

There are many more authors and thinkers who have to be included as important parts of the intellectual context of Luhmann's writings: Herbert Simon's influence on Luhmann's organization theory and Luhmann's intuitions on bounded rationality. There is an early and extensive reception of many authors of General Systems Theory, among others Ludwig von Bertalanffy and Ross Ashby. Others who contributed significant insights included: Kenneth Burke, Gaston Bachelard, Robert K. Merton, Donald T. Campbell, Reinhart Koselleck, Erving Goffman, Humberto Maturana, Henri Atlan, Gregory Bateson, George Spencer Brown, and Franz Heider.

There are patterns in his ways of absorbing influences. Luhmann had encyclopedic reading interests. His main dislike applied to authors who were stronger in normative than in cognitive arguments. He did not prefer establishment figures. Even in disciplines not his own, he was willing to be inspired by outsiders. What in legal discourse is called the 'prevailing opinion' did not impress him; he took nearly forgotten authors from obscurity and gave them a central role in theory building (cf the paper on Vauvenargues, Ch. 7 in SA3). Furthermore, Luhmann had an uncanny talent for finding just the right interpretation for strange ideas from other disciplines. Though there were numerous social scientists who experimented with Maturana's concept of 'autopoiesis,' only Luhmann's variant survives today.

Theory of Social Systems

Luhmann called his contribution to sociological theorizing 'Systems Theory' (early papers in SA3), formulating the continuity to General Systems Theory and to Talcott Parsons. Systems theory is still one of the most influential paradigms of sociological thinking and research, and it is held together by the fact that the concept of social system functions as *the core concept*, which is in itself the object of incessant reformulation and interdisciplinary renewal.

Function and Causality

There was one alternative self-designation Luhmann used in the sixties. His 'functional–structural theory' was meant as an inversion and alternative to the Parsonian 'structural–functional theory.' By this, Luhmann indicated that his theorizing does not start with given social structures that are subsequently analyzed in their functionality (a *modus operandi* he attributed to Parsons). Instead, the sociologist is supposed to begin with social problems, which are understood as functional references – e.g., How to ensure future need fulfillment by present action? How to ensure interpersonal consistency in experiencing the world? Real social structures are then analyzed in their capability to contribute to the resolution of these problems. What becomes visible here is Luhmann's preference for a historical and comparative functionalism, which always compares alternative structural patterns in their ability to contribute to the solution of relevant social problems. This is near to Darwinian evolutionary biology or to certain types of evolutionary economic institutionalism (the Veblenian tradition) and articulates a preference for comparative studies against a conventional preference for the causal reduction of observed events. The methodology of this kind of equivalence functionalism was the subject of Luhmann's first extended sociological essay (SA1: Ch. 1), and he always remained true to this comparative and evolutionary interpretation of the methodological tendencies of sociological systems theory, although he did not write much about functionalism in later years.

System and Environment

As soon as the differentiation from Parsons lost its symbolic relevance, Luhmann rarely used 'functional–structural theory' as a self-description of his theory, instead using 'systems theory.' In the early years, 'cybernetic' was sometimes added by Luhmann to 'systems theory' (SA1, p. 132, n. 16) to mean selectivity of the relations of the system to its environments. There are three interesting implications in this definition. First, selectivity becomes a universal attribute of any event, which ever happens in a system. Second, the environment becomes relevant as a circumstance, which impacts on any selection event in the system. And, third, in choosing *its* selection events and observing *its* environments the system acquires a self-referential character. Therefore, Luhmann's systems theory is emphatically a system–environment theory specified by its cybernetic (i.e., self-referential) character. From the relevance of the concept of 'environment' follows one more methodological postulate. Systems theory not only needs to be comparative in cognitive operations; it must also, in observing alternative

strategies and trajectories of social systems, explain these operations on the basis of the observation of its environments by the system.

Another central term for the analysis of a system and its environments is complexity. A system consists of certain elements and realizes in a selective way relations among them. Luhmann called this property of a system 'complexity.' The complexity of a system seems to be related to the demands its environments place on it.

Meaning and Social Systems

Up to this point, we have not specified which kind of system we are speaking about. In the case of Luhmann, the primacy of social systems is obvious. Though Luhmann had broad interests in cybernetics, biological theory and numerous other disciplines, he left no doubt that he only intended to contribute to the theory of social systems.

What is the basis of the specificity of social systems? This is 'meaning' (Ch. 2 in Habermas and Luhmann, 1971), a special case of a theorem in General Systems Theory, which says that in any system one observes a production of surplus possibilities and of mechanisms reducing these surpluses. Meaning is that way of dealing with surpluses in which the possibilities not chosen are not eliminated, but are remembered and virtualized and thereby stored for future use. Meaning systems that consist of a mix of realities (realized possibilities) and virtualities (as yet unrealized possibilities) need more sophisticated mechanisms for dealing with the kind of complexity they produce.

Social Systems and Psychic Systems

Meaning allows us to distinguish social systems from biological systems, physiochemical systems, and machines, all of which are not able to produce and to process meaning. But there is one further type of systems – psychic systems – for which meaning is constitutive of its operations.

As was the case in Parsons, social and psychic systems are conceived by Luhmann as two different types of systems, separate from one another but coupled via media such as meaning and language. In Parsons, the distinction of social and psychic systems was introduced via the 'action frame of reference' and they represent two of the four types of action systems, which contribute to the emergence of action as a phenomenon constitutive of the human condition. In Luhmann, we have a different constellation. All the hierarchical levels we have in Parsons disappear in the strictly nonhierarchical theory of Luhmann. Instead, we have a clear disjunction of social and psychic systems, both of them being environments for the other type of system. This way it is more explicit that persons and their psychic systems are *only* environments of social systems (and social systems are *only* environments of psychic systems). This diagnosis was perceived as antihumanist and therefore aroused numerous controversies. Luhmann liked to turn these arguments around and to insist that for a person the autonomy from the structures of social systems is an important freedom.

But how is this strict separation of two system types, both of which operate on the basis of 'meaning' and which are connected by language, to be explained? Luhmann developed a theory that the emergence of a system happens by the self-specification of the elements, which are constitutive of the system. The differentiation of social and psychic systems is then explained by the differentiation of elements characteristic of these two systems.

In looking at psychic systems, Luhmann developed a conception akin to Husserl's. Psychic systems consist of thoughts as their elementary basis. Thoughts are connected with one another, referring to earlier thoughts and preparing ongoing considerations (Luhmann SA6: Ch. 1–4). Conceived this way, Luhmann calls psychic systems 'systems of consciousness.' From this, the implication is that there is no systematic place for a concept of the unconscious, except in postulating an observer who ascribes latencies to a psychic system, which are unobservable for the system.

Action and Experience

What are the elementary constituents of social systems? In a classical sociological understanding, one probably would have opted for 'actions,' e.g., the 'unit acts' of Talcott Parsons, and for some years Luhmann described the basic social elements in this way, making use of terms such as 'communicative action.' At the same time, he complicated the understanding by introducing a distinction between 'action' and 'experience' (Luhmann SA3: Ch. 5). Social systems are postulated to process selections for which there exist two alternatives: They are either causally attributed to one of the social systems, or alternatively are seen as representing objective circumstances in the world, which one is unable to influence in the present situation. This distinction of action and experience is no ontological distinction, which identifies ontological properties of the selection events. It is only based on attributions produced by the social systems that can be disputed and reversed. This argument demonstrates how much social systems exist in a social world entirely produced by themselves and how much objectivity (information about states of the world) and subjectivity (selections for which actors can be held responsible) can reverse their roles. But what does this say about the constitutive element of social systems? We cannot point to 'selection' since selection is a general phenomenon at the basis of natural as well as social systems. And there is a clear argument against 'action,' since 'action' is one part of the distinction of action and experience, both sides of which are in the realm of the social. Therefore, we have to look for another concept, which allows us to identify the boundaries of the social domain.

Communication and Action

Until the late 1970s, Luhmann sometimes said that he hesitated whether he should designate 'actions' or 'communications' as the elementary constituents of social systems. One could perceive a rhetorical aspect in these remarks as Luhmann had already established the thesis that in social systems only some selections are attributed to a social system as its actions and therefore the concept of social action could not claim the universal status needed for *the* constitutive element of a social system.

The other candidate for elemental status was obviously communication, a concept until that point sociologists mainly used casually. Parsons never formulated a theory of communication, though since the information theory of the 1940s communication was a probable candidate for a general sociological theory. To understand the fundamental character of information transfer in social processes, social action would have been a counterintuitive choice. Already in 1951, there was a book by Jürgen Ruesch and Gregory Bateson *Communication: The Social Matrix of Psychiatry*, which gave a good idea of how to base a social science discipline on the concept of communication.

For these reasons Luhmann, in the theoretical treatise he finally published in 1984, resolutely established his theory of social systems as a theory of communication systems (Luhmann, 1984: Ch. 4). Communication is the foundational element of social systems and as such it even constitutes the boundaries of social systems. Social systems only consist of communications and there is no communication outside of social systems, which means there is a sharp boundary separating social systems from those environments that do not consist of communications.

Luhmann regards communication as based on three selections, which are indispensable components and are necessarily intertwined: 'information,' 'utterance,' and 'understanding.' Information can be interpreted in the way Bateson proposed: an information is "a difference which makes a difference," a conception requiring a kind of minimum sociality. There must be an entity at which the first difference occurs and a second entity, which registers the first difference and attributes informative relevance to it. The first and the second entities can be identical (I observe the change of my bodily states and ascribe informative relevance to them), but even here exists an internal division, which establishes some 'internal sociality.' Information in this interpretation is not yet communication, but there is subjectivity involved that infers the informative relevance of the differences observed. For communication to arise there must be further components in the communication process. There always has to be a system that explicitly and intentionally decides to *utter* the informative difference. Besides these intentional utterances, we can concede the possibility of nonintentional utterances. For example, I may change my appearance in a way, which is perceived as a kind of utterance that informs others about changes of my mind. This utterance component in a communication process may be called the action component, since there always will be an attribution that classifies the utterance as the action of a specific system. Information and utterance still do not suffice to produce an elementary communication. To realize a communication one needs *a second system, which understands the information uttered by the first system*. Luhmann's concept of 'understanding' is a rather formal one, which does not demand that 'understanding' is a correct or good understanding. It includes the possibility of 'misunderstanding' as a case of understanding. Even if I grin in listening to sad news, this counts as an indicator for understanding to other participants and probably points to the acceptance or rejection of the news (e.g., I do not believe the news or it is good news for me). My acceptance/rejection has to be seen as a fourth component of communication, which already is part of the next communication.

Communication Theory and Double Contingency

Luhmann's three-component theory of communication is related to theories proposed by Karl Bühler and John Searle. It is important to bring to mind the most important sociological understandings assumed by Luhmann's theory: (1) Communication is not dependent on the intention to communicate, utterances can be unintentional. There are always two systems (processors) involved; for communication the second system observes a difference of information and utterance. (2) Communication's medium can be language or nonverbal communication, thus what can be done with it obviously differs. (3) For the competition between 'action' and 'communication,' Luhmann found an elegant solution. The primacy of communication is obvious. But among the components of elementary communications, there is one – the utterance – which functions as the action component. This allows a more general understanding regarding the concept of action as constituted by attributions. If for a selection one looks for someone whose responsibility one wants to claim, one will attribute this selection to this system as its action. (4) As we already saw, understanding as the third component can immediately pass into the fourth component acceptance/rejection, which is already part of the next communication. This argument makes visible communication as a flow and the recursivity built into this flow, that is, communications coming back to or referring to earlier communications. (5) A precondition of any communication is that at least two systems or processors (or 'alter' and 'ego' in the terminology from phenomenology) participate in it. Parsons as well as Luhmann thematize this condition in terms of a theory of 'double contingency,' which Parsons invented in *Toward a General Theory of Action* (1951). Double Contingency means the paradoxical reciprocity of both systems being oriented in their actions and expectations toward what the other system is probably going to do, and the uncertainty arising from this situation (Luhmann, 1984: Ch. 3). Theories of double contingency have to demonstrate – and both Parsons and Luhmann tried to solve this problem – how communication, order, and system formation happen to arise in a situation in which, at the beginning, a reciprocal blockade seems the most probable outcome.

Communication Elements as Events and Operations

Are there plausible arguments against the status of communications as elementary constituents of social systems? One should not adduce the complex character of communications as an objection since unit acts or atoms as elements also have a complex internal structure. But as elements, communications do not seem to possess the internal (temporal) stability, which one might demand as a condition for element status. Some years before he adopted communication theory, Luhmann was already beginning work on the specific temporality of the elements of social systems. In one of his most fascinating essays, *Time and Action – A Forgotten Theory* (1979), Luhmann proposed a solution he attributed

to the French moralist and enlightenment philosopher Vauvenargues (SA3: Ch. 7).

The elements of social systems are 'events.' An event is something that has only vanishing duration. As soon as it appears it is already gone, thus in any social system there is the imperative to incessantly produce new events, which connect to earlier events that are just vanishing, otherwise the system might come to an end. This is a remarkable interpretation considering the equilibrium and stability postulates of social theory in the 1950s.

Luhmann adds one more concept. This is the 'reproduction of event-based elements.' Reproduction is not identical reproduction but new event-based elements have to relate to earlier elements in the system and their constructive freedom is restricted by the history of the system. For this reproduction of event-based elements, Luhmann proposes the name 'operation.'

This operative reformulation of sociological theory necessitates significant changes in systems theory. For example, one can no longer speak about complexity in the way Luhmann introduced this concept in the late-1960s: Complexity as selectivity in the relations between the elements of a system. Now the same structure arises in each individual operation of a system, which means that already on the level of the elements the demands are fulfilled, which in earlier systems theory were seen as macroproperties of whole systems. This is clearly said in *The Society of Society*:

> In principle the classical concept of complexity is sabotaged by the concept of operation as it transforms the distinction of element and relation into one unitary concept (Operation = selective relationing of elements).
>
> 1997: 139, n. 181

Self-Reference, Autopoiesis, Operational Closure

This changeover to an operative understanding of social systems requires a number of far-reaching rearrangements. The first, going back two decades to his idea of cybernetic systems theory, is the increasing importance of the concept of 'self-reference.' From environmental perturbations the system selects those which it needs to stabilize or optimize its *Eigenstates*; self-referential control is also valid for the reproduction of the event-based elements of the system. This immediately connects to the concept of 'autopoiesis,' which Luhmann borrowed from Humberto Maturana and Francisco Varela. Autopoiesis means that everything that functions as a unity in a system – element, operation, structure, boundary – is due to the production processes of the system itself. It follows that on this level of the production of the unities constitutive of a system, no external elements can be imported and the system has to be conceived as an operationally closed system.

Operation and Observation

A last important addition regards the concept of operation. We take from the theory of meaning and from information theory the insight that operations are always based on differences. Operations choose a certain option and discard others always based on a distinction. In social systems or psychic systems, it is often such that both sides of the distinction are represented (options not chosen at least being remembered). An operation for which this is true, Luhmann calls an observation. Thus one can say that each observation is an operation as it depends on its operative performance. On the other hand, in social systems, there are many operations that one could not call an observation as they simply happen without the differences on which they are based being represented.

Like theorists from Harold Garfinkel to Anthony Giddens, Luhmann postulates that modern social systems are based in acts of observation and self-observation. Luhmann gives a more precise version using a term introduced by Heinz von Foerster: Observation in modern social systems, especially in function systems, is always 'second-order observation.' Observers do not have direct access to reality; they observe other observers and using these observations decide with which observations to connect, and from which to dissociate. Modern science that always observes on the basis of observations published by other scientists is a good example of this indirectness in the function systems of modern society.

Theory of Society

The theory of social systems presented above is, in Luhmann's view, the most general social theory sociology can produce. It has a formal similarity to the 'action frame of reference' in the Parsonian *oeuvre*. Luhmann planned this theory as one of two core projects, the other was to conceive a theory of society, society being understood as the most extensive social system including all communications and actions.

Interaction, Organization, Society

To understand the theory of society one has to know that among the multitude of social systems, there are three types on three *levels* of system formation to which he ascribes special prominence. Luhmann calls them 'interaction,' 'organization,' and 'society.'

Luhmann's theory of interaction is very close to Erving Goffman's theory of the interaction order (SA2: Ch. 2). Interaction systems only demand physical presence of the participants and reciprocity of perception. Interaction systems are limited, they can only process one subject matter at a time and when the copresence of participants ends, the interaction systems also end. But they are common, they are repetitive, and they crystallize social forms. Therefore, they account for a significant part of our everyday experience.

Organizations or *formal organizations* define an intermediary level of system formation (Luhmann, 1964, 2000). They are membership organizations based on formalized conditions for entry and exit. As a member, one is bound to the rules of an organization. As autopoietic systems, organizations are operationally closed on the level of decisions. At the end, everything that happens in an organization comes from a decision (e.g., decisions on membership) or leads to decisions and these decisions have to be attributed to the organization itself.

Society is the most extensive social system, including all interactions and organizations in its purview. Luhmann defines society via communicative attainability and derives the

conclusion that today there is only one societal system on earth, which he calls 'World Society.' That was a provocative thesis, first published in 1971 (SA2: Ch. 4), which for some time – until the onset of globalization theory – found neither much notice nor much disagreement.

What does the theory of society Luhmann finally published in the year before his death (1997) look like? Over decades Luhmann developed the theory in four big threads. In the youngest of these threads, society is understood as a system incessantly producing self-observations and self-descriptions (Luhmann GS 1–4; 1982; 1997: Ch. 5). The other three threads are closely related to Luhmann's theory of meaning (Habermas and Luhmann, 1971: Ch. 2) and distinguish a social, a temporal, and a material dimension of meaning. These three dimensions are connected to the theory of symbolically generalized media of communication (social dimension), the theory of sociocultural evolution (temporal dimension), and differentiation theory (material dimension).

Theory of Symbolically Generalized Media of Communication

Regarding the social dimension of meaning, the most important problem seems to be how it is possible to bridge differences of opinion and of interest among participants and achieve the acceptance of unexpected selections by participants. Language, especially language that is made use of in an effective way, is a medium of communication to achieve this. Since Greek and Roman antiquity language was supported by rhetoric as an art, that is, as a technique for improving the effectiveness of those intentions which one pursued, the same social function (effectiveness in communication) was reintroduced into modern society by symbolically generalized media of communication (Luhmann, 1997: Ch. 2).

In contrast to Parsons who ascribed to exchange media, a special function for mediating input–output processes between systems, Luhmann analyzes symbolically generalized communication media as mechanisms internal to systems. Such mechanisms arise primarily in situations where you need additional means of motivation for especially improbable demands. Why, for example, should I accept that another person buys goods, which I would like to have myself? Luhmann proposed the symbolically generalized medium of money. The buyer of much sought-after goods has to hand over a significant amount of money, which symbolically signals to all other owners of money that their money gives them, too, the freedom to buy because as a general medium money can be exchanged against any goods. In a similar way, but with changing motivational constellations, Luhmann analyzes the other media: *Love*: There is someone who completely realigns his actions with the way I experience the world and this motivates me to reciprocate his/her love. *Power*: I am motivated by the negative sanctions a power-holder controls and which I want to evade. *Truth:* I am motivated by reliable ways of experiencing the world promised by science and of which I know that all rational others have to accept them. This is the basic argumentative figure, which is supplemented in Luhmann by a long catalog of media properties: *binary code structures in media* (beautiful/ugly, true/wrong, lawful/unlawful); *probabilities of inflation and deflation of media symbols; mechanisms which connect the media with body perceptions of participants* (sexuality, physical force, physical needs) (Luhmann, 1975). It is easily perceived that this theory, handled as a comparative theory of different media constellations, has its analytical value in these possibilities of systematically comparing types of effective communications.

Theory of Sociocultural Evolution

The second part of the theory of society looks at *changes of social structures in long-term perspective*. Instead of 'modernization,' 'social change,' or 'development' as relevant theoretical paradigms (1997: Ch.3), he pleaded for a neo-Darwinist evolutionary theory. This was a surprising choice as 'evolution' was then a discredited position in social theory. Donald T. Campbell, an American psychologist and methodologist, was one of the few persistently trying to revivify evolutionary interpretations of social science problems. For Luhmann's approach two factors were important. First, he was fascinated that chance events can become productive for the formation of social structures. He perceived this as the conceptual core of evolutionary theories and it is well adapted to other aspects of his theorizing. Second, Luhmann saw the main task to be in a theory of evolutionary mechanisms. The catalog of evolutionary mechanisms – variation, selection, stabilization/retention – and the conviction of their conceptual centrality Luhmann took from Donald Campbell. His main questions aimed at the identification of these three mechanisms in different social systems.

On the macrolevel, Luhmann locates the *variation mechanism* in the possibility to say *no* which is given in any communicative situation and which if used always implies the possibility of changed impulses in a system. The *selection mechanism* consists in the binary codes of the media of communication to which he ascribes the function to sort new meaning elements arising on the basis of negations. The *stabilization of selected meaning complexes* happens via system formation, that is, by the differentiation of a (new) system, which specializes on the material dimensions of meaning becoming prominent in the selection processes. The stabilization of a system has the effect that it becomes easier to see where further possibilities of negation and change are located in the reorganized system. This retroactive effect from stabilization to variation demonstrates a circular connectedness of the three evolutionary mechanisms. In looking at this theoretical construction, one perceives an internal representation of the three threads of the theory of society. There is one mechanism that stands for the probability of chance, a second mechanism focused on selective acceptance of improbable meaning demands, and a third mechanism that reorganizes the material complexity of the world by differentiation processes.

Differentiation Theory

Looking at differentiation theory, the third prominent part of the theory of society, we are near the core of the sociological tradition (1997: Ch.4). The main innovation Luhmann added was interpreting differentiation as a theory of *system formation*. Differentiation processes always produce new system–environment differences. This differs from the binary- and

AGIL-logic of the Parsonian paradigm with Luhmann substituting the idea that for the formation of systems there exist only a limited number of forms. The problem of *changing forms of systems differentiation* becomes the conceptual core of his differentiation theory.

There is first of all *segmentary differentiation*. Segments can be identified by the sameness of their internal structures and by the equality of their societal importance and rank (kinship groups in a tribal society are an example). As Durkheim postulated, in a segmentary society one can add or take away segments without effecting significant changes in the structure of society.

A second form that Luhmann added on the basis of historical evidence is the *differentiation of center and periphery*. A classical illustration is the differentiation of city and country, which postulates systematic and institutionalized differences in the control of resources and information. However, the place of this form of differentiation in the systematics of differentiation theory is not entirely clear since it would be difficult to argue that center/periphery brings about new types of social systems. It seems more convincing that center/periphery is either a distinction internal to a system or a form of interconnectedness among systems that remain separate otherwise. Therefore center/periphery is probably not a differentiation form of its own and *mainly organizes historical transfers between forms of differentiation*.

The third form of differentiation is called *hierarchical differentiation or stratification*. It divides society into social systems (estates, castes, strata), which are distinguished by inequalities of rank. Each of these systems defines for its members a total life form, which does not need other contexts of participation even though there are occasional contacts with other strata. All the traditional high cultures of human history were stratified societies, which demonstrate the historical centrality of this differentiation form.

Functional differentiation is, for Luhmann, the differentiation form of a modern world society, which consists of macrosystems for economic relations, politics, law, religion, science, and numerous other functional contexts. All of these are global macrosystems of worldwide communicative extension. Among one another, they are characterized by extreme social and cultural diversity, which excludes any possibility of a rank order among them. What distinguishes them from segmentary structures is that all these function systems are indispensable. Luhmann called them *self-substitutive orders* where a deficit of any functional resource (e.g., money, power) cannot be substituted for by resources from another function system. As the hypothesis of the 'functional differentiation of world society' is the central empirical hypothesis of Luhmann's theory of society, the future impact of his theory will be dependent on the influence of this hypothesis on global sociological theorizing and research.

Profile of Theory Building and Relevance for Future Social Science

One of the most conspicuous features of the writings of Niklas Luhmann is a strong belief in the validity and cognitive strength of theoretical thinking. Theory for him primarily meant conceptual work, and in this he had close affinities to the cognitive style of Roman law and of philosophy. Luhmann never would have considered himself a philosopher, but for him the philosophical tradition was a treasure trove of conceptual resources, which sociology could neglect only at considerable cost. One example of the value of his conceptual focus is his transformation of the blunt Parsonian concept of contingency from simply dependence into the scholastic concept defined by the double negation of chance and necessity. This way he created a more flexible conceptual instrument.

Interdisciplinarity was, in Luhmann's case, a logical corollary of his stance toward the philosophical tradition. In the development of his theories, he continuously imported concepts from social psychology, cybernetics, linguistics, biology, and logic. And the conceptual structures and theories he imported were then completely sociologized. A remarkable case is *autopoiesis*, a biological concept of circular production processes of biological macromolecules, which Luhmann transferred to the communication-based function systems of modern society. This is a controversial operation but on one point, there cannot be any dispute: there are not even traces of materialism or biologism in the sociological theory resulting from the transfer.

Marxism was an important context in the development of Luhmann's theories. When Luhmann's scientific work became visible in the late-1960s, the intellectual scenery in Germany was dominated by the student movement and its intellectual accompaniments. Luhmann became famous in 1971 when he published a book with Habermas, the main representative of the Frankfurt school (Habermas and Luhmann, 1971). In the following years, the career of systems theory in Germany was coupled with the demise of Marxism. After the mundane and middle-range sociology of the 1950s and 1960s, the intellectual opposition of the late 1960s had reestablished the expectation that sociology should deliver complex theories of society. When Marxism and political economy failed, systems theory was the only alternative remaining. Luhmann had no sympathy for the intellectual and political claims of Marxism, but systems theory was perfectly adapted to an expectation structure looking for macrotheories of society and their universalizing claims.

The structural functionalism of Talcott Parsons was the theory that Niklas Luhmann started from. This was an unusual intellectual relation: On the one hand, Luhmann reconstructed point to point, often taking up minor theoretical distinctions hidden in appendices of the essays on generalized media of exchange. On the other hand, the theory Luhmann built via this reconstructive effort is completely different from the Parsonian undertaking: An open, inductive list of function systems supplanting the deductive logic of AGIL; 'World Society' superseding the solidarity-based national communities Parsons postulated; neo-Darwinist evolutionary theory pushing away the Parsonian thinking in developmental trends; a loose, heterarchical arrangement of interdisciplinary borrowings substituting for the hierarchical conceptual structure of the Parsonian paradigm. When today's systems theory is one of the few elaborated and universalistic paradigms of sociological thinking, which probably will have an influence far into the twenty-first century, this is due to

the ever changing theory-building and theory-reconstructing venture advanced by Niklas Luhmann.

Systems theory such as Luhmann took over from Parsons and the cybernetic tradition, by giving it a new twist as a nonhierarchical theoretical landscape in a nonhierarchical society, stands out among sociological paradigms because of its sociological universalism, not being tied to specific problem situations but instead being applicable to the whole range of sociological problems from minuscule microcontexts to world society, and from long-term historical interpretations of the evolution of human society to the most recent developments in communication practices and technologies. This universalism is not achieved via a rigorous simplification of the conceptual apparatus (as may be the case in rational choice sociology). Instead, it is achieved by an inclusive, interdisciplinary, and historically informed network of sociological theories, which are only loosely coupled under the umbrella of systems theory. This is probably the main attractor of present-day systems theory.

Luhmann's *Social Systems*: Meaning, Autopoiesis, and Interpenetration

Kenneth C Bausch, Institute for 21st Century Agoras, Cincinnati, OH, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The problem of double contingency and its accompanying parable of the black boxes informs Luhmann's conception of meaning and frequently provides illustration at critical junctures. In life, (we) 'psychic systems' and (societies) 'social systems' are constantly faced with situations that require choices. Our *meanings* develop from those choices. Each choice that we make is an element of our meaning. *Autopoiesis* forms the background of Luhmann's theory. Psychic and social autopoietic systems live by constantly maintaining their reproduction as a closed system. At the same time, they constantly interact with their environment by incorporating elements from it and releasing unneeded elements back into it. In this process, what remains the same is the reproductive process, which incorporates those elements that foster its life and evolution. Interpenetration describes how closed autopoietic systems come to share meaning and come to cooperatre and understand each other.

The Problem of Double Consistency

To a large extent, Luhmann's theory of social systems can be understood as an extended solution to the problem of double contingency.

What happens when two psychic or social systems interact? Luhmann examines this situation by reconsidering Parson's problem of double contingency. He states this paradox as follows: "Action cannot take place if alter makes his action dependent on how ego acts and ego wants to connect his action to alter's" (1995: p. 103). (All references to Luhmann, unless otherwise indicated, are to Luhmann, *Social Systems* (1995)). Double contingency involves two closed self-referential circles with no asymmetry and therefore no communication or common action. This situation "concerns a basic condition of possibility for social action as such. No action can occur without first solving this problem of double contingency" (p. 103).

Luhmann reframes the problem of double contingency in terms of 'black boxes' in order to make it independent of existing personalities and applicable to social systems as well as psychic systems.

> Two black boxes, by whatever accident, come to have dealings with one another. Each determines its own behavior by complex self-referential operations within its own boundaries. What can be seen of each is therefore necessarily a reduction. Each assumes the same about the other. Therefore, however many efforts they exert and however much time they spend (they themselves are always faster!), the black boxes remain opaque to one another.
>
> p. 109

How can these black boxes become white for one another?

When black boxes encounter one another, they are forced to integrate each other into their meaning systems. Because they lack insight into each other, they devise stratagems. Ego attempts to determine alter's behavior by assuming what it will be. Then ego sensitively observes alter's behavior to see what happens. Ego soon discovers that alter's behavior cannot be calculated by ego's expectations. In the mutuality of this discovery, ego and alter grant freedom to one another and to themselves. In addition, ego comes to realize that it is assuming how alter will act, and that alter knows that ego is assuming.

A situation of mutual recognition is established. Ego and alter concentrate on each other's input–output behavior, and learn to see themselves as functioning as the other does. They try to influence each other and learn from what happens. In this process, they create a social system. Luhmann says:

> In this way, an emergent order can arise that *is conditioned* by the complexity of the systems that make it possible *but that does not depend on this complexity's being calculated or controlled*. We call this emergent order a social system.
>
> p. 110

A social system, then, does *not* rely on ego and alter seeing through each other and definitely prognosticating each other. A social system is *not* built upon such basal certainties; it *is* built upon social uncertainties and the mechanisms that ego and alter put in place to regulate their dealings with those uncertainties. In Luhmann's words:

> The social system is a system because there is no basal certainty about states and no prediction of behavior to be built thereon. Only the uncertainties *that result from this* are controlled, and they are controlled only with reference to the participants' *own* behavior. System formation constrains (=structures) the possibilities of *safeguarding one's own behavior* in any such situation … The absorption of uncertainty runs its course by stabilizing expectations not by stabilizing behavior.
>
> p. 110

In the ongoing dynamic set up by the condition of double contingency, ego and alter build up structural values by projecting and testing their expectations. They structure their experiences according to these structural values and thereby create an emergent social reality.

Luhmann uses double contingency as a leitmotif throughout his theory of social systems. Black boxes (autopoietic systems), interacting through crafted expectations and careful scrutiny, make moment-to-moment selections that generate social systems and personal meaning. With this parable, Luhmann clearly illustrates how double contingency provides the requisite uncertainty for communication and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32201-2

evolutionary progress. Luhmann uses his solution of double contingency to build the structures of the social world, including meaning, role, norm, program, and value. The black box parable is part and parcel of Luhmann's theory of autopoiesis.

Meaning

Luhmann begins his theory by establishing a new conception of the idea of 'meaning.' He does *not* base his concept of meaning on the content of a statement, some particular fact in the world, or some 'meaning of life.' Instead, he focuses on how human experience is ordered. "A direct and presupposition-less approach to the problem of meaning is then best sought in a phenomenological description of what actually presents itself in meaningful experience" (1990: p. 25).

He begins with the fundamental insight of Husserl that every experience is an experience of something; that knowledge is *intentional*; that is, every experience intends (points to) something outside of the experiencer.

The basic experience of intentionality contains the following interrelated elements:

- transcendence,
- recognition of actuality and potentiality,
- overabundance of possibilities (complexity),
- a need to reduce this complexity that requires choices about what to notice and what to do (selection),
- the contingency of this selection, and
- the negation of possibilities that are not selected.

Underlying this experience is the assumption that a self-referential subject experiences the difference between its actuality and potentiality; makes contingent selections; and retains its negated choices in memory.

Transcendence is built into our experience because we are always attending to things that are beyond our boundaries. Not only that, we attend to outside things with an awareness that they are outside us. This outside–inside awareness is accompanied by *actual–potential awareness*. We experience what we are at the moment (our actuality) and anticipate what we might become (our potentialities) should we choose one or another of our present options.

To continue living, we have to process the *overabundance of possibilities* that confront us by attending to one and negating the others. By that *selection*, we integrate our actuality with the transcendence of one of our possibilities. We have no guarantees in our selections; we never know if we are actualizing the *right* possibility. "In practice, then, complexity means the necessity of choosing contingently, the necessity of accepting risks" (1990: p. 26).

The *negation* involved in selection has 'functional primacy' (1990: p. 27). When we negate the possibilities that we do not select, we do not eliminate them entirely; we merely bracket them; we keep them as the world background of our experience. Negation makes this bracketing possible because it has a reflexive quality; it can be applied to itself. Therefore, with every selection–negation, we maintain the assurance that our negations will not obliterate everything, and that the world will still be there when we need it.

Provisionally, then, at this point in our discussion, meaning is a selection that simplifies experience and maintains the complexity of the world. It simplifies experience by selecting the objects of experience and action. It maintains the complexity of the world through the reflexivity of negation that brackets the nonattended to world out of our immediate experience, but maintains it as background reality. Because of this reflexivity of negation, meaning emboldens us to face the risks of contingency that would otherwise immobilize us in irreversible life and death decisions. This understanding of meaning fits seamlessly into Luhmann's theory of autopoiesis.

Autopoietic systems straddle the system–environment interface. They define themselves as being in opposition to their environments. They constantly recreate themselves in their elements and processes, while they maintain their separateness from their environment and interact with it constantly. They exist only by creating themselves. If they stop creating themselves, they die.

At the same time, they gather energy, nutrients, and the building blocks of their elements from their environments. They "use the difference between system and environment within themselves for orientation" (1995: p. 9). They are closed systems that maintain their closure at all costs, but they establish that closure by the rules of selection they use in utilizing aspects of their environment.

Psychic and social autopoietic systems reproduce processes of meaning. They make selections from the information that faces them. The reflexivity of negation preserves the nonselected elements of complexity as the enduring horizon of their experience. Their self-referentiality provides them with a way to self-determine their selections, so that they are active creators of their meaning and are not merely altered by outside influences. In their self-referentiality, they process new meaning on the basis of old meanings. They are constantly circulating meanings.

The elemental act of meaning is a selection made by a psychic or societal system as it momentarily reproduces itself. This selection determines the elements and processes it will have till its next reproduction. Over time, psychic and social systems evolve together; they accumulate common successful selections. "This co-evolution has led to a common achievement… We call this evolutionary achievement 'meaning'" (1995: p. 59).

Meaning reduces the risk involved in our experiences and actions by providing redundancy, that is, the assurance that lots of people and lots of our own ideas redundantly indicate the same thing. Through redundancy, our meanings gather psychological and social conviction, and they simplify the process of making new selections. In this manner, meaning does not supply any particular answer or course of action; it supplies only the assurance of redundancy for something or another. Meaning, then, has a reach that is universal but without content.

An autopoietic system is constantly referring back and forth across the system–environment interface as it generates meaning from information. Its closure enables it to selectively appropriate (meaning) elements from the total expanse of complexity that faces it. Without closure, it would have no continuity. With closure, it can generate meanings secured by

redundancy and negatable negation from anything in its complex internal and external environment.

As it generates meanings, an autopoietic system recognizes its own relatively simple and redundant meaning as something it can change. On the basis of its autopoiesis, it separates complexity into inner ('self') and outer (environment). It neglects the overwhelming and variable complexity of its environment except when that complexity intrudes on its meaning as information, that is, as "a difference that makes a difference" (Bateson).

Because of our autopoietic status, we have to choose meanings from moment to moment. As a result, 'meaninglessness' is impossible in experience because a decision to call something 'meaningless' is itself a selection that creates meaning. "Meaning is an unnegatable category, a category devoid of difference [whose negation as] meaninglessness is … possible only in the domain of signs and resides in a confusion of signs" (p. 62).

"Meaning is basally unstable, restless, and with a built-in compulsion to self-alteration" (1995: p. 65). Moment to moment, our meaning orientation has to change to deal with new information. "The instability of meaning resides in [this] untenability of [our] core of actuality" (1995: p. 65). Still we keep our balance because our actions open new possibilities within new horizons.

[Our] ability to restabilize is provided by the fact that everything actual has meaning only within a horizon of possibilities indicated along with [it]. And to have meaning means that one of the possibilities that could be connected up can and must be selected as the next actuality, as soon as what is actual at the moment has faded away, transpired, and given up its actuality out of its own instability … Meaning is the unity of actualization and virtualization, of reactualization and revirtualization, as a self-propelling process (1995: p. 65).

Our choice negates the rest of our options by bracketing them and thereby puts us at risk and in a state of imbalance. We deal with this risk by being extremely sensitive to the new situation that confronts us with some of the old bracketed world and with new possibilities; that is, we adjust to a new horizon. Our actuality is unstable and faced with necessary selection; our potentiality is contingent and maintains stability through its gradual change. We pick our way through rough country by making steps that may advance us on our way and may not. We alertly check our relation to our new horizon with each step as we select our next movement.

Building Social Structures through Communication

In the ongoing dynamic set up by the condition of double contingency, ego and alter build up structural values by projecting and testing their expectations. They structure their experiences according to these structural values and thereby create an emergent social reality. These realities develop as meaning formulations that have a degree of transparency for reciprocal observation and communication.

Some of the basic concepts, so formed, are those of person, intelligence, memory, and learning. These realities cannot be observed within black boxes. They are projected substrates for understanding mutually observed behaviors, substrates reinforced by redundant projections. 'Person' indicates that ego cannot observe how acquaintance with alter provides security about what alter will probably do. In other words, alter acts autonomously but with a logic similar to ego's. 'Intelligence' indicates that ego cannot observe how alter chooses one and not another solution to a problem. 'Memory' indicates that "one cannot observe how one complex, actual state of a system passes over into the next, so that one must fall back instead on selected past inputs" (p. 111). 'Learning' indicates that ego cannot observe how information triggers far-reaching consequences in alter. These examples show that:

> It would be futile to seek a psychic or even organic substrate for such things as person, intelligence, memory, or learning. All this concerns observer stratagems for interpreting what cannot be observed and transferring it to the emergent level of contact between systems.
>
> p. 111

Because ego and alter cannot calculate each other's behavior, they concede freedom to one another and limit themselves to knowledge that helps them handle contingency. With this stratagem, they reduce the complexity of the selections that they face. Because they do not see into their companion's black box, they are "bound to the experience of action," what their companion does, and they are "steered by the concession of freedom" (p. 112).

The experience of contingency relates to environments outside the black boxes and therefore beyond the bounds of intrasystem relations. Ego and alter both experience themselves as having environments. Therefore, they relate their experience to those environments as well as to actions. "The generalized result of constant operation under the condition of double contingency is finally the social dimension of all meaning, namely, that one can ask for any meaning how it is experienced and processed by others" (p. 113). In this way, the improbability of the social order (how could a society be exactly such and so) is explained as being normal.

The problem of double contingency solves itself when ego tells alter, "I will do what you want if you do what I want" (p. 117). This proffered agreement is built on the freedom of both parties: "I do not allow myself to be determined by you, if you do not allow yourself to be determined by me" (p. 117). This agreement is the extremely unstable core structure around which social systems crystallize. The core structure and social system built up on it will collapse, if they are not constantly renewed.

In the experience of double contingency, ego sees alter as an alter ego, that is, as an ego with a different perspective. Ego also realizes that alter sees him as an alter ego. Both ego and alter experience this situation as unstable and unacceptable. "In *this* experience the perspectives converge, and that makes it possible to suppose an interest in negating this negativity, an interest in determination" (p. 122).

This interest in determination leads ego and alter to tackle the problem of communication. It is the factually effective catalytic agent that brings it about.

In their mutual recognition of alter egos, ego and alter reach the understanding that is basic to communication. To overcome their impasse of double contingency, they externalize their

expectations for each other with the action of utterance. The intended content of that utterance and alter's reaction to it constitute information for both ego and alter. Understanding, utterance, and information constitute the essence of communication for Luhmann. Each of these elements is a meaning selection event in the ongoing communications that constitute society. The underlying understanding of mutual recognition, for example, is a contingent selection to treat alter as alter ego. An utterance, such as a smile, is an expectation selectively put forward to express tentative friendliness and to test alter's friendliness. Alter's return smile constitutes information that is either selected or rejected by ego as a return offer of tentative friendliness.

Each of these selections is made on the basis of difference *and* unity. The overall unity is the system–environment in which systems define themselves self-referentially as different from their environment. Information is the selection from difference that enhances a system's unity. Utterance is the selection from a system's store of information and coding. Understanding is a selective action that distinguishes between information and utterance.

The difference *between information and utterance* is crucial for the emergence of communication. In recognizing this difference, ego and alter realize that their utterances are contingent, which they must be conditioned upon commonly accepted meanings. On the basis of this realization, ego and alter can build stores of shared meanings. Luhmann says,

> Communication emerges only if this last difference [between information and utterance] is observed, expected, understood, and used as the basis for connecting with further behaviors. Thus understanding normally includes more or less extensive misunderstandings; but these are always … misunderstandings that can be controlled and corrected.
>
> p. 141

Systems and Environments

An autopoietic system creates the differences between itself and its environment by the selections it makes. When a system makes selections, it differentiates its internal complexity from the greater complexity of its environment. It places greater relevance on internal events/processes and endeavors to arrange them. It considers external events/processes to be rather irrelevant, and largely ignores them. In this way, "the system acquires freedom and the autonomy of self-regulation by indifference to its environment" (p. 183). Thus, the difference between an autopoietic system and its environment is not a metaphysical either/or. It is the result of selections made by a system as it reduces its complexity. As they create boundaries and selectively process their inputs and outputs, systems create themselves as centers of their worlds.

A psychic or social system uses differences to generalize and respecify events; it builds the internal *structure* that steers its internal processes without "point for point correspondences with this relevant environment" (p. 184). It creates its identity in *reflection* by identifying itself as what it can control and what continues to recur, and identifying its environment as everything else. On all three levels, the difference of relative complexity provides the standard of autopoietic identity. "Identity in contrast to everything else is nothing more than the determination and localization of difference in relative degree of complexity" (p. 184).

In their ongoing selections of complexity, meaning systems create distinctions in their environments and cocreate the objects they perceive. They gradually build a world of objects as these objects undergo a continual flux of contradiction, reorientation, and redundancy in a constantly reorganizing environment. This understanding of the origin of differences radically deontologizes objects. Under this interpretation,

> [There is] no unambiguous localization of any sort of "items" within the world nor any unambiguous classifying relation between them. Everything that happens belongs to a *system* (or to many systems) and *always at the same time* to the environment of other systems.
>
> p. 177

Autopoietic reproduction also guides the internal differentiation of a system. These systems reproduce not only their internal elements, but also their ability to reproduce. Luhmann puts it this way:

> The connection between reproduction and differentiation becomes comprehensible if one views reproduction, not as the identical or almost-identical replication of the same (e.g., as replacing supplies), but as a constantly new constitution of events that can be connected. Reproduction always implies reproducing the possibility of reproduction.
>
> p. 189

For social systems, this autopoietic reproduction continually reenacts the condition of double contingency. Every momentary event of a social system presents it with a challenge to adapt its structure to fit new complexity, *and* the possibility to generate within itself a new subsystem. In this process, a system evolves complexity and includes system–environment differences within itself.

Luhmann illustrates this situation by describing the situation in which a man might offer a light to a woman smoker.

> At a party one sees a woman reach for a cigarette, and (if she dawdles suggestively), one may offer her a light from one's own cigarette lighter. [In this situation,] settled differentiations stabilize the possibilities for reproduction by constraining conditions on the comprehensibility of communication and the suitability of behavioral modes. But the meaning surpluses that must be produced alongside provide ever further chance for innovative system formation; in other words, they provide the chance to include new differences and new constraints and thus to increase the ability to constrain the initial situation via differentiation. Only thus can system complexity increase.
>
> p. 189

Subsystems like this social one make improbable states become probable. They make possible the increase and normalization of organized complexity for the system. In our example, the interaction that provides the light may lead to a date and may lead to many otherwise improbable eventualities (like the man and woman going to a parent–teacher conference with their child).

Such improbable internal self-differentiations build subsystems upon an already pacified environment. They presuppose a social situation that is already rather regulated. The woman's dawdling with the cigarette is understood as an invitation to conversation. The conversation is understood as the basis for further mutual self-revelation, and so on.

Because of differentiation, each subsystem orients itself only to its own system–environment difference and its part of the system's overall complexity. It assumes that other reproductive requirements of the system are fulfilled by other subsystems. At the same time, each subsystem reconstructs the whole system. Because of the circular dependence of parts and wholes, each shift within a system rearticulates the self-reference of the whole system.

Action

The story related above illustrates an ever-present sequence of how social structures come to be. The woman sends an ambiguous message; the man responds to the message. These two actions are both momentary (they have a very short duration), but they form a relationship that is the basis for further events and deeper relationships, which may develop as in the story or lead to other consequence because of different choices.

The idea of action is based upon the fundamental and radical notion of an *event*. An event is a temporal atom, an indivisible, all-or-nothing happening. An action is such a momentary all-or-nothing happening. As such, it passes away as do all events in time, yet it "brings about a total change in past, present, and future … It gives up the quality of being present to the next event and becomes a past for it (i.e., for its future)" (p. 287). By passing away, an action provides maximum freedom vis-à-vis time to its successors and to the system that they constitute.

Boundaries

Social systems constitute themselves by communicating meanings. Through meanings, they establish their boundaries. In Luhmann's words, "The difference between system and environment is mediated exclusively by *meaning-constituted boundaries*" (p. 194). A system expands its boundaries every time it reproduces itself by incorporating new meaning. At the same time, it also redefines its boundaries by excluding elements of its environment. Each such event "makes a relation and with it a boundary decision" (p. 195).

Every communication is based upon an expectation that it will be heard. It "stakes a claim. At the very least, it demands time and attention" (p. 195). If it is accepted and if it contains new themes, it extends the system's boundaries, and enmeshes its speaker in the ongoing communicative action.

Meaning-constituted boundaries are self-generated boundaries that are regulated within the system itself. Systems are guided in their processing of new themes "by what has already occurred, by what is possible in a situation, and by general structures of expectation" (p. 197). Such structures of expectation help one to "foresee in detail how and about what one should communicate in the supermarket, on the football field, at lunch, at home …" (p. 197).

The World with Many Centers

Every autopoietic system creates centrality for itself by differentiating itself from its environment. If it does not do that, it exists in the state of undifferentiated innocence, 'the state of grace,' in which centrality is meaningless. With meaning-constituted boundaries, systems begin to have a *world*. They experience themselves, their environment, and everything that functions in it as an element, as a selection within a horizon that includes all possibilities and indicates further ones, that indicates an end and a beyond, that is both necessarily and arbitrarily bounded from anywhere within it (p. 207).

Systems correlate meaning and world. They position every meaning that they create within a world of previous meanings. They assume the existence of that world as background for the specification of every meaning.

The *world* becomes an ultimate concept that describes the *unity of the difference between system and environment* … an ultimate concept, one free from further differences … [It is a] unit of closure subsequent to a difference. It is the world after the fall from grace (p. 208).

In this world, the pride of centrality is removed from the subject. The center of the world is created by each system–environment difference that constitutes the world.

Every difference becomes the center of the world, and precisely that makes the world necessary: for every system–environment difference, the world integrates all the system–environment differences that a system finds in itself and its environment. In this sense, the world has multiple centers – but only so that every difference can fit the others into its own system and environment (p. 208).

Interpenetration

Systems that are environments for each other can couple their structures in such a way that they increase their independence from environmental determination by increasing their dependence on each other. By this process of 'structural coupling' (Maturana and Varela, 1987), two or more systems form a more complex integrated whole, while retaining (even increasing) their individual capabilities. In meaning (psychic and social) systems, structural coupling is described as interpenetration.

A system can make its own complexity, which involves indeterminacy, contingency, and the pressure to select, available to another system that can use that complexity for its own system-building. In doing this, it is said to have 'penetrated' the second system. From that point on, the behavior of the penetrating system is codetermined by the receiving system. When the Internet presents itself to me, for example, what happens on the net is codetermined by the use I make of it.

Interpenetration exists when penetration occurs reciprocally, "when both systems enable each other by introducing their own already-constituted complexity into each other … This means that greater degrees of freedom are possible in spite (better: because!) of increased dependencies" (p. 213).

As individuals try to communicate, they create the noise that generates social systems. "Social systems come into being on the basis of the noise that psychic systems create in their attempts to communicate" (p. 214). This 'noise,' or complexity, creates

pressure to select a meaning without specifying what meaning. As a result, it presents risk, freedom, and negatability to a system.

In this noisy situation, a system tentatively advances an expectation and then sensitively attunes itself to psychic and social feedback. If its expectation is denied, it learns to negate that expectation. If its expectation is affirmed, it is reassured and, in the course of time, it may become redundantly reassured. With redundancy, two or more systems set the stage for further ventures into noise.

When systems interpenetrate, they do share elements, but they share those elements from individual perspectives. As Luhmann says,

> Interpenetrating systems converge in individual elements-that is, they use the same ones-*but they give each of them a different selectivity and connectivity*, different pasts and futures. Because temporalized elements (events) are involved, the convergence is possible only in the present. The elements signify different things in the participating systems, although they are identical as events: they select among different possibilities and lead to different consequences.
>
> p. 215

In this way, autopoietic systems share meaning elements while maintaining their own autonomy.

Interpenetration connects the autopoieses of organic life, consciousness, and communication. These three forms of autopoiesis condition each other. "Autopoiesis qua life and qua consciousness is a presupposition for forming social systems" (p. 218). Conversely, "the social system, based on life and consciousness, makes the autopoiesis of these conditions possible in that it enables them to renew themselves constantly in a closed nexus of reproduction" (p. 219). In all of their interpenetrations, autopoietic systems use the complexity of their contributing systems, but they do so on the basis of their being autonomous. On both sides of structural coupling, there is "the *difference* between and the *interlocking* of *autopoiesis* and *structure* (the one continuously reproducing, the other discontinuously changing) … between *organic/psychic* and *social* systems" (p. 220).

This discussion of meaning, autopoiesis, and interpenetration touches merely upon the structural aspects of Luhmann's social theory. How we maneuver within his autopoietic world would involve us in discussions of:

- morality
- socialization
- expectations
  - persons
  - roles
  - programs
  - values
  - normative
  - cognitive
- structural change
- contradiction
- self-reference
- epistemology

Abstract

Aleksander Romanovich Luria, known best as a pioneering neuropsychologist, conducted basic research on human cognitive and emotional functions between the early 1920s and the mid-1970s. His scientific career is reviewed; special emphasis is placed on the ways in which Luria's approach to neuropsychology is best understood in light of his lifelong quest to create a unified approach to understanding human development as a biocultural, social process.

Aleksander Luria (1902–77) is best known as the father of neuropsychology. However, analysis of his full career indicates that neuropsychology occupied only part of Luria's career and life project, which was devoted to the development of a unified psychological science. This biographical sketch follows Luria from his early research on objective methods of psychodiagnosis, through a series of studies on the cultural history and ontogeny of complex psychological functions, ending with his work on neuropsychology and his efforts to combine the study of general laws with the study of individual human functioning.

Aleksander Luria was born in Kazan, an old Russian University town east of Moscow on 16 July 1902. He entered Kazan University in 1918 at an unusually early age of 16 years owing to the social disorganization (and associated opportunities) associated with the Russian Revolution. He obtained his bachelor's degree in 1921 at the age of 19. In 1923, he moved to Moscow where he remained for the ensuing 54 years (with the exception of a period between 1942 and 1945 when he directed a clinic for rehabilitation of soldiers who had suffered brain injuries). During this long career, he taught and conducted research at a variety of important institutions including the Institute of Psychology, the Department of Psychology at Moscow State University, the Institute of Defectology, and the Bourdenko Institute of Neurosurgery. He died in Moscow on 14 August 1977.

While an undergraduate student, he established the Kazan Psychoanalytic Association and planned on a career in psychology. His earliest research sought to establish objective methods for assessing Freudian ideas about abnormalities of thought and emotion as well as the effects of fatigue on mental processes. His dream was to create a unified psychology that would encompass both the intimate personal thoughts and emotions of individuals, as well as the biological and social conditions that supported such processes (Luria, 1979). As he summarized his notions about psychoanalysis:

> Here, I thought, was a scientific approach that combined a strongly deterministic explanation of concrete, individual behavior with an explanation of the origins of complex human needs in terms of natural science. Perhaps psychoanalysis could serve as the basis for a scientific reale Psichologie, one that could overcome the nomothetic-idiographic distinction.
>
> Luria, 1979

In emulation of the psychoanalytical writers, he conducted clinical research on free associations, but he mistrusted the results of such efforts, feeling that any conclusions he tried to reach about the flow of his subjects' thoughts were insufficiently grounded. As he wrote in his autobiography, "While I was able to fill notebooks with (a patient's) free associations, I was in no position to carry out my plan to use such data to capture the concrete reality of the flow of ideas" (Luria, 1979).

In response to this dissatisfaction he created a methodology designed to embody a psychodynamic theory of mind in an objective set of laboratory procedures. The centerpiece of this methodology was an experimental technique that he called the combined motor method, which, he hoped, would provide a way of rendering Freud's clinical methods accessible to experimental treatment.

The fullest existing description of this work is contained in a monograph published in English under the title *The Nature of Human Conflicts: Or Emotion, Conflict and Will* (Luria, 1932). Luria explicitly rejected mechanical determinism in psychological analysis, declaring that "The structure of the organism presupposes not an accidental mosaic, but a complex organization of separate systems … (that) unite as very definite parts into an integrated functional structure" (Luria, 1932).

This approach required Luria to solve the following problem. Since this structure is the consequence of a long complicated development, both ontogenetically and cultural-historically, and because the parts are integrated into a whole functional system, how can it be possible to isolate elements in this system for purposes of psychological analysis? Phrased differently, since no two people are constructed alike, how could one possibly obtain valid evidence about the thought processes of another person?

The answer that Luria provided was that other people's thoughts can only be revealed indirectly in so far as they can be reflected in a publicly displayable, voluntary behavior. He phrased his strategy as follows:

> We should on the one hand, produce the central process of the disorganization of behavior; on the other hand, we should try to reflect this process in some [other] system accessible and suitable for examination. The motor function is such a systematic, objectively reflected structure of the neuro-dynamic processes concealed from immediate examination. And there lies before us the use of the motor function as a system of reflected structure of hidden psychological processes. Thus we proceed along the path we call the combined motor method.
>
> Luria, 1932

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61081-4

The first phase in his technique was to induce a well-coordinated, publicly available behavior as the medium of coordination necessary for the psychological analysis to be accurate. He used various devices for this purpose. Often the subject was requested to hold the left hand steady in a device that could record its movements, while simultaneously being asked to press a button or squeeze a bulb in response to verbal stimuli presented by the experimenter. Once this behavior became stable, the analyst sought to disrupt it selectively in line with his hypothesis about particular internal psychological states.

The combined motor method was applied to psychodiagnosis in a wide variety of real-life circumstances consistent with Luria's goal of demonstrating the possibility of a methodology powerful enough to reach beyond the laboratory to engage the kinds of long-term emotions that typically organize human behavior. For example, it became the basis for early lie detector tests and later for studies of the role of speech in the development of normal and mentally retarded children as well as adults suffering various neuroses and brain damage. It also served as the foundation for a great deal of his subsequent research on the relation of culture and human thought. As Luria (1932) expressed this relationship at the end of *The Nature of Human Conflicts*, "The analysis of complex cultural mechanisms is the key to the understanding of the simple neurodynamical processes."

In 1924, Luria had met Lev Vygotsky, a developmental psychologist whose influence was decisive in shaping Luria's future career. Together with Vygotsky and Alexei Leontiev, Luria sought to establish an approach to psychology that would enable psychologists to "discover the way natural processes such as physical maturation and sensory mechanisms become intertwined with culturally determined processes to produce the psychological functions of adults" (Luria, 1979). Vygotsky and his colleagues referred to this new approach variably as 'cultural,' 'historical,' and 'instrumental' psychology. These three labels all index the centrality of cultural mediation in the constitution of specifically human psychological processes, the role of the social environment in structuring the processes by which children appropriate the cultural tools of their society in the process of ontogeny, and the need to study processes of change over time. An especially heavy emphasis was placed on the role of language, the 'tool of tools' in this process: the acquisition of language in early childhood was seen as the pivotal moment in ontogeny when phylogeny and cultural history are merged to form specifically human forms of thought, feeling, and action. From the late 1920s until his death, Luria sought to elaborate this synthetic, cultural-historical psychology in different content areas of the discipline.

During the 1930s, he conducted two lines of research aimed at elucidating the relationship between phylogeny and cultural history in children's development (this topic is often referred to as the 'nature–nurture question'). The first project falls within the scope of what is now referred to as 'cross-cultural psychology.' It seeks to hold phylogeny constant while studying the effect of rapid cultural change.

In one implementation of this strategy, Luria led two expeditions to Central Asia where he investigated changes in psychological functioning brought about by changes in economic activity, social organization, and literacy that were then taking place (this work was only published after a long delay resulting from its ideological implications). In this research, he presented psychological tasks believed to tap such areas as perception, reasoning, problem solving, and self-concept to groups of adults who had, or had not, been incorporated into the Soviet system of collectivized farming or formal system of schooling. He found a marked difference in tested performance as a function of these variations in life experience. The thinking of those people who remained isolated from modern forms of agricultural work or schooling appeared to be dominated by immediate practical concerns bound to particular situations while those who had undergone the modernizing changes sponsored by the state appeared to think in more general and abstract ways that could be applied across a wide variety of situations.

A second line of work on the nature–nurture issue focused on comparisons between identical and fraternal twins exposed to different regimes of deliberate instruction. This work was organized at the Institute of Medical Genetics where hundreds of twins attended a specially organized boarding school. One set of studies involved the performance of identical and fraternal sets of twins of different ages on tasks designed to vary in the extent to which they depended upon cultural knowledge. Luria's basic finding in this work was that the correlation between the performances of identical twins were higher than those of fraternal twins when the tasks they were presented required relatively little specialized cultural knowledge. But the more the tasks required such knowledge, and the older the children were, the closer the correlations between fraternal twins approached the correlations among identical twins. He concluded that as children grow older and acquire more cultural knowledge, the influence of phylogeny over development gives way to the influence of cultural history.

He also conducted a special case study of a pair of identical twins who had developed what appeared to be their own private language before entering the boarding school as young children. For several months one of the twins was provided specialized training in the use of language to guide thinking about a variety of intellectual tasks while the other was not. The twin who received specialized training showed markedly more rapid intellectual development than the untrained twin, although the untrained twin's development rebounded once he, too, was provided specialized training. This result provided converging evidence on the role of culturally organized experience, especially language, on cognitive development (Luria and Yudovich, 1959).

In the late 1930s, largely to remove himself from public view owing to the period of political purges initiated by Joseph Stalin, Luria entered medical school where he specialized in the study of aphasia, retaining his focus on the relation between language, thought, and self-regulation, but now in the context of the politically neutral arena of medical practice. The onset of World War II made his specialized knowledge of crucial importance to the Soviet war effort, and the tragic widespread availability of people with various forms of traumatic brain injury provided him with voluminous materials for developing his theories of brain function and methods for the remediation of focal brain lesions. It was during this period that he developed the systematic approach to brain and cognition that has come to be known as the discipline of neuropsychology.

Several ideas were central to Luria's approach to brain-behavior relationships. First, he conceived of the brain as consisting of three global 'blocks' which underpin and control three associated kinds of brain processes. The first block, sometimes referred to as the 'primary sensory areas,' controls perceptual and motor integration. The second block, which includes the prefrontal and frontal areas, undergirds programing and executive control of thought and action. The third block, which includes the brain stem and paleocortex, controls the level of arousal and activation of the cortex as a whole. In addition to considering the workings of each of these blocks, he was particularly interested in the ways in which these three functional blocks interact dynamically to reconfigure one another in the execution of various neurocognitive processes.

Within this general framework, Luria sought to overcome a classical dichotomy between those who believed in the strict localization of brain functions and those who emphasized the 'equipotentiality' of different parts of the brain in subserving various psychological functions. While he accepted the idea that elementary functions such as the registration of sensations from the retina could be localized in particular groups of cells, he insisted that the systemic structure of complex forms of mental activity characteristic of adult humans represents complex functional systems involving the coordinated action of many anatomical locales. These functional brain systems are themselves mediated by the culturally organized environment, especially its systems of signs. As a consequence, he argued, "to understand the brain foundations for psychological activity, one must be prepared to study both the brain and the system of activity" (Luria, 1979). This insistence on linking brain structure and function to the proximal, culturally organized, environment provides the thread of continuity between the early and later parts of Luria's career. Third, he combined clinical practice with basic research on brain function, taking his ability to create systems of remediation as crucial evidence concerning the adequacy of his theories. Specifically, he believed that by reorganizing the extracortical components of various cognitive processes he could affect a change in the functional neural systems which remained intact in brain-damaged populations, thus leading to remediation of neurocognitive functions thought to be lost as the result of damage to specific brain areas.

Following the war, Luria sought to continue his work in neuropsychology. However, his plans were interrupted for several years in 1948 when he was removed from the Institute of Neurosurgery during a period of particularly virulent anti-semitic repression. For the next several years, he pursued his scientific interests through a series of studies of the development of language and thought among mentally retarded children at the Institute of Defectology. This work used a variation on the combined motor method to explore how the development of self-control is linked to the development of language, and provided a theoretical basis for the development of special curricula for the mentally handicapped.

In the late 1950s, Luria was permitted to return to the study of neuropsychology, which he pursued until his death of heart failure on 14 August 1977. During this period, he continued developing the idea of the brain as composed of functional systems closely linked to the conditions of the proximal environment, producing a number of important monographs on the brain bases of language, memory, and cognition. As this work became known outside of Russia, it gave rise to the development of standardized diagnostic tests (often referred to as the Luria Neuropsychological Battery) which are still widely used in clinical work. Even with the advent of highly sophisticated neuroimaging methods which can more directly localize structural brain lesions, the neuropsychological methods Luria pioneered continue to be the gold standard for understanding the functional impact of disruptions in neurocognition secondary to cerebral insults. Despite the recent explosion of technological innovation (i.e., MRI, PET, spectroscopy, etc.) which has threatened to relegate Luria's methods to footnote status in the neurosciences, what has remained internationally influential are the basic theoretical principles concerning the organization of higher psychological functions into complex functional systems mediated by sign systems and the use of these principles to guide the development of remedial procedures for brain-damaged patients (Christensen et al., 2009). Although not formally acknowledged, Luria's footprint is also quite evident in the recent manifestation of cultural neuroscience which attempts to study *how cultural values, practices and beliefs shape and are shaped by the mind, brain and genes across multiple timescales* (Chiao and Ambady, 2007).

In the years just prior to his death, Luria returned to his early dream of constructing a unified psychology that overcame the centuries-old split between natural and cultural science approaches to psychology. He proposed to do this by showing how theoretical principles arrived at through the experimental study of groups of people ('nomothetic' knowledge) could be made relevant to understanding and coping with the concrete life circumstances of an individual human being (idiographic knowledge). He called the approach combining the two psychologies 'romantic science.' He contrasted romantic science with what he called classical science:

> Classical scholars are those who look upon events in terms of their constituent parts. Step by step they single out important units and elements until they can formulate abstract, general laws …. Romantic scholars' traits, attitudes, and strategies are just the opposite. They do not follow the path of reductionism, which is the leading philosophy of the classical group. Romantics in science want neither to split living reality into its elementary components nor to represent the wealth of life's concrete events as abstract models that lose the properties of the phenomena themselves.

He illustrated his concept of romantic science in two longitudinal case studies involving people for whom ordinary ways of mediating action in the world was impossible (Luria, 1968, 1972). One was a man with a superb, but unusually organized memory. The other was a man who had suffered unusual disorganization of memory owing to massive destruction of the right posterior part of his brain. In each case, Luria combined information from experimental studies of large groups of subjects with the peculiarities of the individual case. His ideas about how the two kinds of processes combine were evaluated by the therapeutic regimes he prescribed.

These two case studies illustrate in dramatic detail his blend of classical, experimental approaches with clinical and remediational approach, a synthesis that stands as a model for psychological research and theory to the present day.

This article is a revision of the previous edition article by M. Schabas, volume 6, pp. 4152–4158, © 2001, Elsevier Ltd.

Abstract

The history of modern macroeconomics begins when much older economic questions were reclassified by Ragnar Frisch under the headings 'microeconomics' and 'macroeconomics.' The history of macroeconomics related here is importantly a history of the relationships of macroeconomics to microeconomics, and econometrics. The emphasis is on the development of macroeconomics as an interplay among economic theory, empirical investigation, and public policy.

The Origins of Modern Macroeconomics

The problems addressed by the field now called 'macroeconomics' are ancient (*see* Macroeconomics, History of up to 1933); yet the modern era begins in 1933 only with the coinage of the terms *macroeconomics* and *microeconomics* (almost certainly) by Ragnar Frisch, who also coined the term *econometrics* at about the same time (Velupillai, 2009). All three terms circulated informally – first, through the newly formed econometric society – before slowly becoming accepted as defining the broadest conceptual divisions of economics. For Frisch, microeconomics concerned the behavior of individual firms or consumers, whereas macroeconomics concerned the economy in its entirety. Practically, macroeconomics must give up on fine detail and deal with aggregated data. The history of modern macroeconomics is importantly a history of its relationships to microeconomics and econometrics.

Econometrics for Frisch was scientific economics and involved the cooperation of economic theory, mathematics, and statistics (Bjerkholt, 1998; Louçã, 2007). Like many others at the time he was concerned especially with *dynamics*, accounts of the movements of economic quantities over time. Jan Tinbergen gave life to the econometric project with the first macroeconometric model, a model of the Dutch economy in 1936. The worldwide Great Depression brought the problem of business cycles into the forefront of economics and debates over a correct understanding of the crisis raged throughout the 1930s. Tinbergen's approach had been pragmatic and not deeply committed to a particular theory.

While John Maynard Keynes never used the term 'macroeconomics,' it was only with the publication of his *General Theory of Employment, Interest, and Money* (1936) that its common theoretical core began to take shape. Keynes argued that earlier 'classical' economists failed to offer a theory of output as a whole, believing that market coordination was sufficiently effective that full employment of labor and capital failed only when market 'imperfections,' such as government regulation or unions intervened. In contrast, Keynes argued that, in complex, monetary economy, perfectly functioning markets may fail to be self-adjusting.

As a matter of accounting logic, aggregate savings in an economy (mainly lodged in financial assets) had to equal aggregate investment (mainly in the form of machinery and other physical means of production). But savers and investors were typically distinct actors: individuals, motivated by thrift, caution, and habitual psychology, made savings decisions; while firms in the face of a radically uncertain future, motivated by subjective expectations of profits, made investment decisions. Interest rates, representing the opportunity cost of real capital relative to financial assets were an important determinant of investment; while income was the most important determinant of consumption and savings. Formal financial markets operating through interest rates were inadequate by themselves to bring the plans of investors and savers into line. When savings plans exceeded investment plans, firms would find themselves with unsold goods and would be forced to cut back production and lay off workers – reducing incomes and bringing aggregate demand (i.e., planned total expenditure) back into line with aggregate supply (i.e., the value of total production), but at the cost of increased unemployment. Highly heterogeneous labor market inhibited the ability of workers effectively to offer to work for lower wages at times when demand for the products of firms fell short of their expectations, resulting in unemployment. The economy could be stuck for long periods in recession. The government could start a virtuous circle, directly stimulating demand through direct purchases, generating incomes that, in turn, generated further demand – a *multiplier* process. More important, the improved estimation of future profits would increase private investment and push the economy toward full employment. Keynes' position was, contrary to Marxist criticism, not that capitalism was doomed to failure. Rather it often – and

sometimes severely – underperformed. Yet, helpful policy interventions were possible.

Immediately on publication, the economics profession began to try to understand and interpret Keynes' *General Theory*. What ultimately came to be called the IS-LM model, due to John Hicks (1937), became the most influential interpretation. Hicks stripped the *General Theory* down to its architectural bare bones, stressing its commonalities with its 'classical' precursors and downplaying its more radical elements, such fundamental uncertainty and coordination failures. Hicks' simple model proved to be easily taught and a useful framework for econometric modeling and mathematical elaboration. While it clearly captured some of the essentials, Keynes, himself trained as a mathematician, was skeptical of the value of detailed formal modeling.

In 1938 and 1939, Tinbergen published a two-volume study based on the first econometric model of the United States economy. Utterly convinced of the wrongheadedness of the econometric project, Keynes published a scathing review (Morgan, 1990).

The World War II and Keynesianism

The General Theory laid the intellectual groundwork for government intervention in the economy; the World War II made it a reality. The war greatly expanded the size of government and the scope of its direct management – over prices, production, labor markets, financial markets, and foreign trade. Such direct management required better data. The theory and practice of national income accounting had been begun in the 1930s by Colin Clark and Simon Kuznets, among others (Kendrick, 1970). The war gave it an enormous practical boost, so that the United States and Great Britain began to publish official accounts shortly after the war with countries around the world quickly falling into line. Electronic computers, originally developed for military purposes, proved a godsend for the development of both data collection and the practical implementation of econometric modeling.

The fear of a postwar depression and the practical success of economic intervention during the war convinced governments that it was both feasible and necessary to take Keynes' advice to actively manage the macroeconomy. The Beveridge Report in Great Britain and the Employment Act of 1946 in the United States committed their governments to a policy of aiming at high rates of growth and low levels of unemployment. Abba Lerner (1943) coined the term 'functional finance' to argue that government policy should not be judged by whether the budget is balanced but by the state of the economic variables that directly affect welfare: income, employment, inflation. Government debt in the US, the UK and many other countries, which had historically been paid off after being run-up in wartime, was in fact maintained at higher levels after World War II than after earlier wars.

Economic management was extended to international trade and finance through the Bretton Woods Conference of 1944, in which Keynes was a key player, that led to the creation of the World Bank and the International Monetary Fund. These institutions in turn gave a boost to the development of international macroeconomics as a distinct discipline.

Microfoundational Programs and Macroeconometric Models

Frisch viewed the macroeconomic context as indispensable for microeconomic analysis. Most economists, however, viewed microeconomics as prior to macroeconomics: the economy as a whole being built out of individuals – explanation must ultimately be grounded in individual behavior. In the second half of the nineteenth century, Leon Walras had provided a vision of an agent-by-agent model of economic interdependence, based on the assumptions of perfect competition. From the 1930s to 1970s, substantial progress was made in formalizing Walras' vision of *general equilibrium*. One program of 'microfoundations' for macroeconomics aimed at discovering what assumptions would be necessary to formulate general equilibrium models that displayed 'Keynesian' features: unemployed resources, scope for beneficial policy intervention, and so forth (Weintraub, 1979; Hoover, 2012). This theoretical program made closest contact to practical macroeconomics in the 'general disequilibrium' models associated with Don Patinkin, Robert Clower, Robert Barro, Herschel Grossman, and Edmund Malinvaud (Backhouse and Boianovsky, 2012). These models emphasized the consequences of *rationing*: firms see potential profit in greater production provided that there is demand; unemployed workers would be willing to buy goods provided that they are hired; but neither is a position to act unless the other acts first; so the economy is stuck.

A second microfoundational program, whose central player was Lawrence Klein, also sought a marriage of Walrasian general equilibrium with Keynesian insights, but was empirically oriented (Hoover, 2012). Klein adopted an aggregate general equilibrium macroeconomic architecture similar to Hicks' IS-LM model, which lent itself especially to quantification and estimation using the new econometric tools developed mainly by the Cowles Commission (Morgan, 1990). Klein's ideal, however, was disaggregation as far as the data would allow. By 1950, Klein had estimated a series of small macroeconometric models of the United States (Bodkin et al., 1991). The twenty-five equation 'Klein–Goldberger' model became the paradigm for later macroeconometric models. Macroeconometric modeling became a 'big science' enterprise, involving large research teams with substantial division of labor over long periods of time. Klein was involved in a series of modeling projects, the Brookings model (about 200 equations in its 1959 version and 400 equations in its 1972 version), the Wharton model, the MPS model (a joint effort of the Massachusetts Institute of Technology, the University of Pennsylvania, and the Social Science Research Council), which later evolved into the FMP model (with the Federal Reserve replacing the Social Science Research Council). Many similar models were developed by other teams – academic, governmental, and commercial – for many countries. Project LINK, which Klein directed under the auspices of the United Nations, attempted to integrate national models into a worldwide model.

The increasing size of the models reflected increasing disaggregation. A major microfoundational effort – both explicitly within macroeconometric modeling teams and as stand-alone research – aimed to provide individual optimizing accounts for each of the main elements of the Keynesian

model. Reacting to empirical findings of Simon Kuznets, for example, alternative microeconomic accounts of the consumption function were developed and evaluated on microeconomic and aggregate data: Duesenberry's (1949) relative-income hypothesis, Friedman's (1957) permanent-income hypothesis, and Modigliani and Brumberg's (1954) life-cycle hypothesis. Some typical instances of similar efforts made for other Keynesian functions, include the demand for money (Baumol, 1952; Tobin, 1958), investment (Jorgenson, 1963), the production function (Fisher, 1969), and labor supply (Lucas and Rapping, 1969).

The ultimate function of macroeconometric modeling in the eyes of Keynesian was to provide the basis for policy guidance. Tinbergen (1956) laid out the 'targets-and-instruments' framework for policy analysis: policymakers set goals and economists, using macroeconometric models, guide their setting of monetary and fiscal policy tools to reach those goals. The economy is viewed as a machine to be manipulated. Keynesian economists widely concurred with the view that the ultimate resolution of the relationship between microeconomics and macroeconomics was less a matter of establishing a theoretical connection than of achieving in Paul Samuelson's (1955: p. vi) phrase "a grand neoclassical synthesis," in which macroeconomic policy would maintain full employment of resources, at which point all the old verities of microeconomics with respect to efficient resource allocation would apply.

Economic Growth

As postwar macroeconomic management appeared to be successful and fear of another 1930s-scale depression faded, macroeconomists turned their attention from business cycles to economic growth (Boianovsky and Hoover, 2009). The turn was, in part, a reaction to the Cold War, which could be framed as a competition between the Soviet Bloc and western democracies – both over economic dominance and over providing a persuasive and workable model for developing economies. Harrod's (1939) dynamic Keynesian model was interpreted as sharing a formal structure with Domar's (1946) growth model, which became a workhorse of development economics. The 'Harrod–Domar' model pointed to high rates of investment as the key to growth in economies with unemployed resources.

In 1956, Robert Solow and Trevor Swan independently criticized the 'Harrod–Domar' model for its assumption of fixed technology and offered a flexible-technology model in which the mixture of inputs can respond to the relative price of labor to capital. A surprising consequence of the Solow–Swan model is that the long-term, sustainable rate of growth does not depend on the rate of investment but only on the underlying rates of growth of the labor force and technology and on the rate of depreciation of capital. The *level* of per capita income nonetheless does depend on the rate of investment. In an empirical study framed by this model, Solow (1957) showed the surprising result that technological progress, rather than capital investment, explained by far the largest part of the actual growth of the United States economy.

Macroeconomists throughout the 1960s elaborated the Solow–Swan model, trying to give compelling theoretical accounts of technological progress and of 'optimal growth,' conceived of as either policies that maximized consumption per head ('golden rule policies') or ones that maximized intertemporally discounted social utility. With the rise of the environmental movement, which challenged growth as a social goal, and with the severe recessions of the early 1970s, growth economics moved to the back burner. By the end of the 1980s, as the business cycle moderated in developed countries, growth economics was revived. The attention was again placed on technological progress, but also on the apparent failure of developing economies to converge toward the performance of developed economies – a prediction of the Solow–Swan model. The 'new growth models' stressed production involving increasing returns to scale in which growth rather than exhausting productive opportunities expanded them, so that the more an economy grows the faster it can grow.

The Monetarist Challenge

Keynes and the postwar Keynesians saw fluctuations in aggregate demand, largely owing to the investment behavior of firms, as the main source of the business cycle, and they saw government policy (mainly fiscal policy) as necessary remediation. *Monetarism* (a term coined in the late 1960s) offered an anti-Keynesian alternative analysis (Mayer, 1978). Unlike Keynesians, monetarists, led by Milton Friedman, presumed that the private sector left to its own devices was fundamentally stable and that ill-conceived government policy was the main source of business cycles.

Friedman revived the quantity theory of money, which is the ancient doctrine of the *neutrality of money* – i.e., the price level in the economy in the long-run is directly proportional to the stock of money. One implication is that a policy that works through increasing the supply of money will ultimately affect only prices and not the quantities of real goods and services or employment, which are the sources of genuine economic welfare. But Friedman offered an important twist: in the short-run transitions between one long-run price level and another, changes in the stock of money could have powerful real effects. Friedman and Anna J. Schwartz's *Monetary History of the United States* (1963) – exhibit number one in the monetarist case – convinced many that the Federal Reserve's having allowed the money stock to fall precipitously was the principal cause of the Great Depression and that smaller recessions generally could be laid at the feet of central banks.

Under the metallic monetary standards that prevailed before World War II, high rates of inflation were largely wartime phenomena. After the war, the world experienced unprecedented secular increases in the price level, and macroeconomists sought the cause. They distinguished, for example, between price increases owing to rising costs of inputs (cost-push inflation) and rising expenditure on output (demand-pull inflation). The Phillips curve documented empirically an inverse relationship between the level of unemployment and the rate of inflation (Wulwick, 1987). Some economists read the Phillips curve as a trade-off: unemployment rates could be lowered provided that we are willing to tolerate higher inflation rates.

Friedman (1968a) argued, first, that there was ultimately only one kind of inflation. Cost-push inflation and inflation owing to changes in the demand for real goods (e.g., increases in government expenditure) were essentially *relative* price changes that provided the information about supply and demand of productive inputs and were essential to the smooth functioning of the economy. They were self-limiting. Only demand owing to increases in the money supply had no natural upper bound and could account for the postwar inflation: "inflation is always and everywhere a monetary phenomenon"(Friedman inter alia 1968b: pp. 18, 98, 105). Friedman argued that the Phillips curve resulted from workers mistaking the rise in all prices (including their wages) for an increase in their real wage, so that they were willing to work at what firms understood actually to be a lower real wage, thus lowering the unemployment. Friedman argued that workers' expectations of inflation would catch up with actual inflation rates and the real effects would vanish. The expectations-augmented Phillips curve (developed independently by Edmund Phelps) displays only a short-term trade-off, and policymakers cannot suppress unemployment below its *natural rate*. Even nonmonetarists rapidly adopted this model of inflation, although sometimes substituting the *nonaccelerating inflation rate of unemployment* for the 'natural rate' to avoid the implication that it was impervious to every kind of economic policy and not just to the management of monetary aggregate demand.

Monetarists argued that the short-term real effects of monetary policy, as they resulted from confusions about price signals, mainly misallocated resources. The economy was too complex, the channels from policy to real outcomes were too inscrutable, and the processes of individuals forming expectations were too unstable for policymakers to calibrate their interventions in reliably beneficial ways. Monetarists therefore advocated that policy should follow simple rules. For example, Friedman proposed that the supply of money should grow at a steady rate of X percent a year, where X was related to the underlying long-term growth rate of gross domestic product.

Monetarism triggered active, and sometimes acrimonious, empirical debates. Gradually, monetarists' views came to dominate at the Federal Reserve and, subsequently, at central banks around the world. Although not a pure implementation of monetarist doctrine, Chairman Paul Volcker's reform of Federal Reserve monetary policy, starting in 1979, and the subsequent collapse of US inflation rates was largely counted as a monetarist triumph. Nonetheless, monetarism remains controversial on theoretical, empirical, and policy grounds – not least, because financial innovation undermined a conceptually stable definition of the money stock, rendering empirical evidence equivocal and money-supply policy difficult to implement.

The New Classical Macroeconomics and the Challenge to Macroeconometric Modeling

One way or another, expectations play a part in each of the principal elements of the Keynesian model, and it was understood early on that empirical measures of expectations would be essential for successful macroeconometric modeling. Early efforts were based on mechanical extrapolations of past data, but these proved to be inconsistent in the sense that the best predictions of the model – i.e., the expectation that the model itself generated – would typically differ *systematically* from the expectation assumed to hold in the model. A systematic error could be easily reduced and might even be profitable to someone who was able to bet in the market against a policymaker informed by the model. John Muth's (1961) *rational-expectations hypothesis* is the simple idea that the expectation assumed to motivate agents in a model must coincide with the best prediction of that same model. Lucas and Rapping in the context of models labor markets and Thomas Sargent in the context of financial markets introduced the rational-expectations hypothesis into macroeconomics around 1970. Model consistency implied that all relevant aspects of the model must be considered simultaneously, which is a daunting technical challenge in models as complex as the macroeconometric models in the tradition of Klein. Early rational-expectations macromodels were small and assumed that all markets clear at all times. Clearing markets and rational expectations typically implies that money is neutral even in the short run: the only real effects of monetary policy are unsystematic, so that policy can add noise to the system but not achieve systematic improvements. Policies that adopt simple, easily understood rules minimize the noise. The *policy-ineffectiveness proposition* and the commitment to policy rules suggested to some that the new approach was a radical 'monetarism mark II.' Initially, some referred to it as the 'rational-expectations school,' but it was soon seen that the characteristic results depended on clearing markets and that the rational-expectations hypothesis could be used even in models with typically Keynesian outcomes, so that *new classical macroeconomics* is a better term for the new approach (Hoover, 1988).

Monetarism had accepted the aggregative structure of Keynesian models, differing over more specific details (Gordon, 1974). Robert Lucas (1976) offered a more radical objection – the *Lucas critique*. Tinbergen saw macroeconometric models as a tool for policymakers guiding their use of policy instruments. Lucas argued that policymakers must be thought of not as standing outside the economy, as Tinbergen's framework suggested, but on a par with other actors within the economy. Those actors observe and anticipate the policies and adjust their behavior accordingly. The aggregate relationships of the macroeconometric model are not, therefore, likely to remain stable in the face of alternative policies. Lucas proposed that the only solution to this problem of *policy noninvariance* is to model explicitly the decisions of individual agents reacting to policy.

The Lucas critique shifted the landscape of macroeconomics. Despite a long history of trying to understand the microeconomics behind macroeconomics, mainstream macroeconomists for the first time insisted explicitly that only models with appropriate 'microfoundations' would be acceptable. The piecemeal approach of the Klein program was rejected in favor of a systemic approach based on a general equilibrium with rational expectations. The technical challenges were, however, insurmountable, and, without much reflection or critical discussion, the profession adopted the

representative-agent model, an approach in which a single (or sometimes a few types of) agent, who maximizes a utility or profit function in the manner of a microeocnomic agent is taken to stand for all agents in the economy (Hartley, 1997). The representative-agent model simply ignores the conceptual and technical problems of aggregation and, in fact, provides the simulacrum of microfoundations and not the genuine article.

Keynesians quickly adopted key planks of new classicism: rational expectations, the Lucas critique, representative-agent microfoundations. They challenged the assumption that markets clear rapidly and suggested various 'frictions' – institutional or economic features that inhibit rapid adjustment of prices or wages to external 'shocks' or to policy actions. Frictions were supposed to provide the microeconomic underpinning of short-run nonneutrality. *New Keynesian* approaches emphasize a range of frictions, including contracts, menu costs, efficiency wages, imperfect competition, informational asymmetry, and coordination failures (Mankiw and Romer, 1991). Some approaches require going beyond strictly representative-agent models, but the departures are rarely very large. The payoff is to better identify sources of aggregate fluctuations and to preserve a scope for beneficial policy intervention.

The weakest point of early new classical models was the inability to explain business cycles, which was the main opening for the new Keynesian challenge. Lucas constructed a new classical monetary business-cycle model in 1975. Random shocks make some periods more productive than others, and forward-looking workers and producers are more active in these periods – a boom. Long-lived capital goods add dynamics, transmit transient booms to the future, and smooth the transitions, so that booms and busts are stretched over longer periods. Lucas' model was not empirically successful, but it provided the template for further developments. Most notably, Kydland and Prescott (1982) developed a model in which random shocks to the productivity of technology was the main driving force of the cycle. For some time, such *real-business-cycle models* dominated the new classical research agenda, with successful modifications trying to improve the empirical match (Hartley et al., 1998).

The New Neoclassical Synthesis

By the mid-1990s the debate between new classicals and the new Keynesians had cooled. The effort to improve the empirical fit of real-business-cycle models had forced new classicals to consider additional sources of fluctuations than technology shocks and to integrate price adjustment or other frictions into their models. But the larger theoretical template of the real-business-cycle model – rechristened the *dynamic, stochastic general equilibrium* (or *DSGE*) model – became the workhorse for business-cycle analysis (Duarte, 2012). Soon a *new neoclassical synthesis* was declared.

For practical monetary-policy analysis, the new neoclassical synthesis focused on a simple, aggregate model that was regarded as a kind of summary for a microfoundationally adequate business-cycle model. The paradigm model included a forward-looking investment–savings relationship (IS curve), an expectations-augmented Phillips curve, and a monetary-policy rule governing the setting of short-term interest rates. The main use of the models was to evaluate counterfactually the performance of alternative monetary-policy rules. These models, along with the DSGE models, found widespread acceptance in central banks around the world, sometimes coexisting uneasily with older-style macroeconometric models, which had fallen out of favor with academic economists in the 1970s.

The development of macroeconomics has frequently been shaped by events in the world: the Great Depression, World War II, the oil price shocks of the 1970s and 1980s. The worldwide recession and financial crisis beginning in December 2007 appears to be another such shock. It exposed weaknesses in currently popular macroeconomic models. Models frequently lacked a financial sector, limiting their relevance to the main element of the crisis. The assumption of rational expectations and the absence of heterogeneity among agents made it difficult to capture or to characterize the mechanics of the asset price boom that preceded the crisis or its sudden collapse. The radical reaction among economists is that the financial crisis challenges the fundamental basis on which modeling – at least since the 1970s – has preceded: fundamentally new macroeconomic thinking is in order. The conservative reaction acknowledges the incapacities of current models, but sees their foundations as essentially sound: extension and development of the existing lines of macroeconomic thinking will suffice. Research proceeds along both lines. It is too early to offer a historical assessment.

Macroeconomics, History of up to 1933

Robert W Dimand, Brock University, St. Catharines, ON, Canada

Abstract

The field that became known as macroeconomics emerged from long and rich traditions of monetary theory, business cycle analysis, and discussion of economic growth. Macroeconomics is the analysis of aggregate levels and rates of change of output and employment, the price level (and its inverse, the purchasing power of money), the interest rate, and the balance of payments. This field had a long history before it received its name with Ragnar Frisch's (1933) distinction between macrodynamics and microdynamics and before John Maynard Keynes' General Theory of Employment, Interest and Money (1936). This article analyzes the 'prehistory' of the concept – the various strands of economic thinking that coalesced in about 1933 to produce modern macroeconomics, i.e., roughly the history of macroeconomics up to Keynes. The subsequent history is covered in a companion article, "Macroeconomics, history of, from 1933 to the present."

Macroeconomics, the analysis of aggregate levels and rates of change of output and employment, the price level (and its inverse, the purchasing power of money), the interest rate, and the balance of payments had a long history before the field received its name with Ragnar Frisch's (1933) distinction between macrodynamics and microdynamics and before John Maynard Keynes' *General Theory of Employment, Interest and Money* (1936).

Prehistory

Three currents of analysis and discussion, overlapping but distinguishable, emerged on subjects later considered macroeconomics, coalescing in the 1930s. The theory of money and prices began with the quantity theory of money as an explanation of the 'Price Revolution' of the sixteenth century and of balance of payments adjustment under the gold standard (Grice-Hutchison, 1952; Locke, 1991; Gervaise, 1720; Hume, 1752; Christiernin, 1761; Monroe, 1923; Hegeland, 1951; Vickers, 1959; Guggenheim, 1989), was extended to inconvertible paper currency during the French Revolution and Napoleonic Wars (Thornton, 1802; Murphy, 2009; Arnon, 2011), debated Jean-Baptiste Say's law of markets and the possibility of a general glut of commodities at the end of the Napoleonic Wars (Sowell, 1972; Link, 1959; Corry, 1962; Green, 1992; Baumol, 1999; Davis, 2005), and achieved analytical sophistication during the Banking School–Currency School–Free Banking School debates (Fetter, 1965; O'Brien, 2007), culminating in Walter Bagehot's treatment of the lender of last resort in *Lombard Street* (1873) and then in the contributions in the 1890s by Alfred Marshall, Irving Fisher, and Knut Wicksell, the three theorists appropriately pictured on the cover of David Laidler's *The Golden Age of the Quantity Theory* (1991a); the interwar flourishing of monetary analysis of saving–investment adjustment (Eshag, 1963; Bridel, 1987; Jonung, 1991; Laidler, 1999; Dimand, 2003; and sources reprinted in Wood and Capie, 2000). A second approach, brought to prominence by Clément Juglar (1862) and W. Stanley Jevons (1884), viewed that fluctuations in production and prices are cycles, oscillations with more or less regularity in amplitude and periodicity, producing a vast literature sampled by D.P. O'Brien (1999), Harald Hagemann (2001), and Mauro Boianovsky (2005), and leading to the creation in the interwar period of business cycle research institutes such as the National Bureau of Economic Research (NBER) (Mitchell, 1927; Kondratiev, 1997; Glasner, 1997). Histories of crisis theories, and particularly of theories of periodic crises, have been published as early as E. von Bergmann (1895) and Edward D. Jones (1900), with histories of the phenomenon of crises going back to M. Wirth (1858). Thirdly, François Quesnay's Physiocratic *Tableau Économique*, tracing the circular flow of spending and income in the economy as whole, was followed by the 'magnificent dynamics' of classical economists such as David Ricardo, Thomas Robert Malthus, and John Stuart Mill, exploring the paths of population, production, and wage and profit rates as a growing economy approached a stationary state (Eltis, 1984; Davis, 2005; Brewer, 2010), with the beginnings of formal algebraic models of economic growth sketched by J.C.L. Simonde de Sismondi and developed in Karl Marx's "schemes of simple and expanded reproduction" (Arthur and Reuten, 1998) and a false dawn of modern growth theory in with Allyn Young (1928) on increasing returns to scale and economic growth, Frank Ramsey (1928) on optimal capital accumulation, and Grigorii Fel'dman (1928) on the growth rate in a planned economy.

These extensive pre-1933 contributions to what would later be called macroeconomics raised issues that resonate in later macroeconomics (as the terms New Classical and New Keynesian indicate, as do Divisia monetary aggregates (François Divisia, 1925), Ricardian equivalence, Schumpeterian creative destruction). The work of Milton Friedman and his students revived the quantity theory tradition (see Friedman, 1956). Michael Woodford's *Interest and Prices* (2003) harks back to the analysis of a pure credit economy in Knut Wicksell's *Interest and Prices* (1898). Christopher Sims' vector autoregression (VAR) approach to modeling economic fluctuations without assuming too much a priori knowledge of the underlying model is, with more modern statistical techniques, in the spirit of Wesley Mitchell's NBER statistical

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03058-0

approach to business cycles, starting with time series analysis of fluctuations rather than with theoretical models (an approach that produces the concept of leading indicators). Irving Fisher, although spectacularly mistaken about whether stock prices had reached a permanently high plateau in October 1929, shaped macroeconomic analysis and practice through the Fisher equation relating real and nominal interest, the Fisher diagram for intertemporal consumption smoothing, indexed bonds, distributed lags, the Fisher ideal index number (the geometric mean of the Paasche and Laspeyres indexes), and, especially since the credit crunches of 2007 and 2008, his debt deflation theory of depressions (see e.g., Korinek and Mendoza, 2013), with Ralph G. Hawtrey's concept of a credit deadlock and the Mises–Hayek Austrian trade cycle theory also attracting renewed attention. Central bank responses to the credit crunch were informed by the fact that Ben Bernanke of the Federal Reserve, in his doctoral dissertation, and Mervyn King of the Bank of England, in his European Economic Association presidential address, had studied the US debt deflation of the early 1930s, with close attention to Fisher (1933), just as monetary policy decisions at the Bundesbank and then at the European Central Bank were informed by acquaintance with the literature surrounding the German hyperinflation of the early 1920s (including Keynes, 1923). Macroeconomics did not begin in 1933 or 1936, although certainly Keynes (1936) provided a transformative focus on the equilibrium level of aggregate output and employment rather than on prices and cycles.

The Theory of Money and Prices

European prices roughly quadrupled from 1530 to 1600, as was documented for English prices by Bishop William Fleetwood (1707), pioneer of price history and of quantification of changes in the purchasing power of money (but because the commodity prices examined by Fleetwood all changed in roughly the same proportion, he did not have to consider appropriate weights in a price index). This 'Price Revolution' occasioned the emergence of the quantity theory of money, described by Mark Blaug (in Blaug et al., 1995) as "the oldest surviving theory in economics" and by David Laidler (1991b) as "always and everywhere controversial." Martin Navarro de Azpilcueta of the University of Salamanca, writing in Latin in 1556, and the French political theorist Jean Bodin in 1568 attributed the rise in European prices to the rise in the same proportion of the quantity of money circulating in Europe, due to the inflow of gold and especially silver to Spain from Mexico and Upper Peru (now Bolivia) and to increased output of European silver mines (see Marjorie Grice-Hutchison, 1952 on the Salamanca School, and Arthur E. Monroe, 1923 and Hugo Hegeland, 1951 on Bodin). Azpilcueta and the other Salamanca writers were the last phase of a medieval scholastic tradition that included Nicole Oresme's analysis around 1360 of how the prince's seigniorage from debasement of the coinage took purchasing power away from the public (Oresme et al., 1989), a discussion that drew in turn on Aristotle's remarks on the functions of money. Isaac Gervaise (1720), Richard Cantillon, P.N. Christiernin (1761), and, above all, David Hume (1752) used the quantity theory of money to analyze the automatic restoration of international payment equilibrium and critique the mercantilist obsession with a balance of trade surplus, holding that in the long run a change in the quantity of money will cause prices and money wages to change in the same proportion, and the money supply will be distributed across countries in proportion to the demand for real money balances in each country. In Hume's price–specie flow mechanism, mercantilist interventions, using tariffs and quotas on imports, regulations, bounties on exports, and monopolies on colonial trade to increase the quantity of money in a country through a trade surplus would, in the long run, just raise prices in the home country and lower prices in its trading partners, reducing net exports until equilibrium was restored. In the short run, an increase in the quantity of money would give a temporary stimulus to economic activity until prices and wages fully adjusted (see Filippo Cesarano, 2007; Arie Arnon, 2011; Dimand, 2013). The specie (gold and silver) that flowed into Spain from its empire in the New World flowed out again in trade. In Adam Smith's critique of mercantilism, closer than Hume's of the twentieth century monetary approach to the balance of payments, the terms of trade would not change for a country that, like Scotland, was small enough to be a price taker in world markets (Humphrey, 1993; Laidler, 2003: Chapter 1; Arnon, 2011). If mercantilist interventions artificially increased the quantity of money in a country, the resulting excess supply of money would be spent on imports and on exportable goods (and on foreign lending), causing the gold and silver to flow out of the country again, until the world money supply was distributed in proportion to demand for real money balances, with money supply equal to money demand in each country.

Although John Law had experimented with inconvertible paper currency in France until the collapse of Law's system in 1720, David Hume, Adam Smith, and their contemporaries analyzed price and payments adjustment under a metallic standard, with gold and silver coin and bullion circulating (see Murphy, 2009, on Law). Following a bank run sparked by reports of a French invasion, conversion on demand of Bank of England notes into specie was suspended from 1797 to 1821. Henry Thornton, the Bullion Committee of the House of Commons, and David Ricardo extended the quantity theory of money to inconvertible paper, conclusively establishing that the rise in British prices during the Napoleonic Wars and the high price of bullion on the Hamburg market (when purchased with Bank of England notes) resulted from the increase in the Bank of England's note issue, an analysis that failed to convince either the Bank's directors or the majority in the House of Commons (Thornton, 1802; Hayek, [1931]1991; Viner, 1937; de Boyer des Roches, 2003; Davis, 2005; Arnon, 2011). The Bank directors insisted that they could not overissue notes as long as they only discounted real bills of exchange to accommodate the needs of trade, forgetting that the nominal volume of trade would grow as prices increased. The directors invoked the authority of Adam Smith for this real bills doctrine, even though Smith's analysis had dealt with bank notes that were convertible into coin on demand. Similarly, John Law had argued in 1705 that a land bank could not overissue notes as long as the notes were created by lending with land as security, overlooking the endogeneity of the price of land.

At the end of the Napoleonic Wars, the sharp reduction in military spending, availability of cheaper grain imports from Continental Europe and the United States, and the contraction of the note issue as the Bank of England moved toward restoration of convertibility at the prewar parity combined to produce industrial and agricultural depression in Britain. The classical theory of rent and of comparative advantage emerged from the classical critique of the Corn Laws, the protectionist reaction to the agricultural depression. Thomas Robert Malthus and J.C.L. Simonde de Sismondi attributed the industrial depression to a general glut of commodities, an insufficiency of effective demand. David Ricardo, James Mill, and Jean-Baptiste Say held that such a general glut was impossible, because people only supply goods, services, and assets because they wish to acquire other goods, services, and assets, so that the industrial depression was a transitional problem, as wage and price signals shifted factors of production from producing commodities in demand during wartime to producing commodities in demand during peacetime (Link, 1959; Corry, 1962; Patinkin, 1965; Sowell, 1972; Green, 1992; Hollander, 1997; Davis, 2005). The problem of transition was not considered by the classical economists as something to be ignored – Say endorsed public works to provide employment during the transition, whereas Ricardo wished to restore convertibility at the depreciated value of notes rather than the prewar parity – but it was a temporary, short-run issue, resulting from a change in the mix of commodities demanded, not from a shortfall of demand in general. Following a tradition going back to Aristotle's invocation of the myth of King Midas, Ricardo, Say, and James and John Stuart Mill held that people sell commodities for money intending to use the money as a medium of exchange, not with the hoarding of money as the ultimate goal. In the debate over what Keynes was to call Say's law of markets (see Baumol, 1999), (aggregate) supply creates its own (aggregate) demand, the classical economists (in Keynes' sense of classical as accepting some form of Say's Law) tried to say something stronger than what Oskar Lange (1942) later termed Say's Equality (the value of excess demand sums to zero in equilibrium over all markets other than money – that is, the truism that the value of aggregate excess demand is zero if excess demand is zero in each market), but weaker than what Lange termed Say's Identity (the value of excess demand sums to zero over all markets except money, at any set of prices, market clearing, or otherwise – which, together with Walras' Law, implies that the money market always clears for any set of prices). Keynes (1933a, 1936) drew inspiration from Malthus' emphasis on the concept of effective demand (demand allowing for quantity constraints: if the labor market is in excess supply, unemployed workers cannot spend on goods the wages they would have earned if employed), even though Malthus' failure to distinguish a decision to save from a decision to invest undermined his response to Ricardo's analysis.

The Bank Act of 1844 and the British banking crises of 1825, 1832, 1836–37, 1847, and 1857 occasioned the debate between the Currency School and Banking School over the appropriate structure and policy of the Bank of England (Viner, 1937; Fetter, 1965; Skaggs, 1999; Laidler, 2003; O'Brien, 2007; Arnon, 2011), with the Free Banking School denying the need for any legally privileged bank of issue acting as a central bank (Smith, 1936). Drawing on Ricardo's presentation of the quantity theory of money and the price–specie flow mechanism, Currency School writers such as J.R. McCulloch, G.W. Norman, and Lord Overstone urged that the Bank of England should act so that a mixed paper and metallic currency would behave like a metallic currency (for instance, a 100% marginal reserve requirement on note issue), and should manage the volume of currency to prevent gold outflows. The Currency School, whose ideas shaped Sir Robert Peel's Bank of 1844, attributed banking crises to mismanagement by the Bank of England. Banking School writers such as Thomas Tooke and John Fullarton emphasized the endogeneity of credit, with the volume of credit more likely to react to changes in prices than to cause them, and with the quantity of banknotes demand-determined. Rather than expecting the Bank of England to be able to prevent gold drains by varying the discount rate, the Banking School wished the Bank to hold a large enough bullion reserve to accommodate temporary balance of payments fluctuations without unsettling credit markets. These debates in monetary theory culminated in Walter Bagehot's *Lombard Street* (1873), the classic account of how the central bank should act as lender of last resort to preserve the liquidity of the banking system, rather than acting as an ordinary bank to maximize the profits of its shareholders.

1886 and All That

The Royal Commission on the Depression of Trade and Industry (Northcote, 1886: p. x) reported "that the trade and industry of the country are in a condition that may be fairly described as depressed; that by this depression is meant a diminution, and in some cases, an absence of profit, with a corresponding diminution of employment for the laboring classes; that neither the volume of trade nor the amount of capital invested therein has materially fallen off, though the latter has in many cases depreciated in value; that the depression above referred to dates from about the year 1875, and that, with the exception of a short period of prosperity enjoyed by certain branches of trade in the years 1880 to 1883, it has proceeded with tolerable uniformity." The same year, the first annual report of the US Commissioner of Labor was on *Industrial Depressions* (Wright, 1886; Barnett, 1941). Lecturing in Scotland on *Irregularity of Employment and Fluctuations of Prices* (Foxwell, 1886: pp. 48, 96), Herbert S. Foxwell, professor of political economy at University College, London (where Knut Wicksell attended some of his lectures that year) and a fellow and lecturer of St. John's College, Cambridge, lamented "the most serious effect of falling prices. They depress industry and trade" leading to what is "of all the many claims of labor, the most grave, the most pressing, and the most just, … the claim I have brought before you to-night, the claim for more regular employment." The literature on depression and unemployment grew until a bibliography on unemployment published by the London School of Economics in 1909 extended to 71 pages (not counting Sidney Webb's Introduction). Many shared Foxwell's conviction that fluctuations in the purchasing power of money caused fluctuations in employment (although formal economic theory, like Foxwell, was vague on the mechanism connecting

the two phenomena). As Foxwell (1886: p. 52 n) noted, "So long ago as 1856, Mr. William Cross ably advocated a monetary standard corrected by means of an index number. See his *Standard Pound v. the Pound Sterling* (Aberdeen, 1856). Another method for securing the same object has recently been proposed by M. Walras" (see Léon Walras' *Théorie de la Monnaie*, 1886, and Bridel, 1997). Alfred Marshall (1887), also of St. John's College, Cambridge, and one of the witnesses before the Royal Commission, tentatively suggested, as a first step toward stabilizing the purchasing power of an index number, symmetallism, a monetary unit of a certain amount of gold plus a certain amount of silver, rather than just one metal, but backed away after Sir Robert Giffen blasted 'fancy monetary standards' that would tamper with the trusted, impersonal, and automatic gold standard (Laidler, 1991a; see also Marshall, 1923, 1926). The possibility of using monetary policy to target a price index (rather than an exchange rate or the price of gold), in the interest of stabilizing output and employment, was a thought that occurred to economists before the twentieth century – and although William Cross is a forgotten figure who was never part of the mainstream of economics, the same cannot be said of Walras or Marshall.

Monetary Theorists and Economic Stabilization

Bimetallists, such as William Jennings Bryan in his "Cross of Gold" speech accepting the Democratic nomination for President of the United States in 1896, saw gradually declining prices as a burden on debtors (especially farmers with mortgages), and proposed to increase the quantity of money and thus raise prices by coining both gold and silver at a fixed price ratio (so that the monetary authority would have the daunting task of fixing the relative price between two metals, a problem that Marshall's symmetallism avoided). J. Laurence Laughlin, a hard-money opponent of bimetallism and an important influence on the design of the Federal Reserve System, responded by rejecting the quantity theory of money, emphasizing the cost of production of gold rather than the quantity of money (Skaggs, 1995). Irving Fisher (1896, 1911) offered a theoretical and statistical defense of the quantity theory (see also Kemmerer, 1907), with changes in the quantity of money determining the price level and short-run real fluctuations, but, contrary to the bimetallists, with money neutral in the long run (Dimand, 2013). Fisher (1896), equating the difference between interest rates in any two standards (gold and silver, money and commodities, two national currencies) to the exchange rate of appreciation of one standard against the other, showed that the price deflation (appreciation of the purchasing power of money) only burdened debtors if the deflation was unexpected. If the deflation was expected, it would be reflected in lower interest rates. With acknowledgment to Marshall's evidence before official inquiries (later collected by Keynes as Marshall, 1926), Fisher (1896) introduced the Fisher equation (nominal interest equal to real interest plus expected inflation), the expectations theory of the term structure of interest rates, and uncovered interest parity between currencies. Covered interest parity, equating the spread between spot and forward exchange rates to the difference between nominal interest rates in two currencies, was added by Keynes (1923) (see Flanders, 1989 on developments in open-economy monetary economics). Modeling expected inflation with a distributed lag of past price level changes, Fisher (1911: Chapter IV, 1926) attributed fluctuations in real economic activity and employment to slow and incomplete adjustment of inflation expectations to monetary shocks, a phenomenon that in a 1928 book title Fisher termed 'the money illusion.' Influenced by Fisher (the only economist he had read at the time of writing Hawtrey, 1913), Ralph Hawtrey of the British Treasury also advanced a monetary theory of the trade cycle (Hawtrey, 1913, 1919, 1932; Deutscher, 1990). From the concluding chapter of Fisher (1911) onward, Fisher advocated a 'compensated dollar,' seeking to stabilize the real economy by stabilizing the purchasing power of money as measured by a price index. To try to make this proposal operational, Fisher identified the geometric mean of the Paasche and Laspeyres indexes as the ideal index number, published a weekly price index, and pioneered the issue of indexed bonds.

While Fisher and Hawtrey stressed monetary shocks and advocated price level stabilization, Joseph Schumpeter ([1912]1934) and Dennis Robertson (1915) saw clusters of entrepreneurial innovations, introducing new products or techniques, as the real shocks driving economic fluctuations (see Presley, 1979 and Fletcher, 2000 on Robertson, and Swedberg's introduction to Schumpeter, 1991). Pigou (1927) argued that waves of optimism and pessimism caused fluctuations in investment. The Stockholm School (Karin Kock, 1929; Erik Lindahl, 1939; Erik Lundberg, 1937; Gunnar Myrdal, 1939) followed Knut Wicksell (1898, 1907, 1915) in emphasizing the distinction between the market rate of interest, set by the banking system, and the natural rate of interest, variously defined as the interest rate at which the price level would be constant, or at which investment equals saving, or which reflects the marginal productivity of capital. Monetary shocks shift the market rate of interest, while innovations and other real productivity shocks change the natural rate. As long as the market rate was less than the natural rate, entrepreneurs would borrow for new investment, causing prices to rise, and the converse occurred when the market rate was above the natural rate. Monetary policy could stabilize the economy by varying the market rate to match changes in the natural rate (which was not directly observable). The process analysis of the Swedish economists, of Robertson (1926), and of Keynes' *Treatise on Money* (1930), while motivated by concern with fluctuations in output and employment, formally modeled price level movements and interest rates, with no explicit theory of unemployment or aggregate income (Patinkin, 1982; Jonung, 1991). Beginning with the first German edition of Mises (1935) in 1912, the Austrian monetary malinvestment theory of the trade cycle drew on the Currency School tradition and on Wicksell to interpret depressions as the necessary corrections of unsound speculative investment resulting from expansionary monetary disturbances, and to reject price level stabilization as interfering with and prolonging necessary deflationary adjustments (Mises, 1935; Hayek, 1931, 1933; Ellis, 1934).

Fluctuations as Cycles

Although they were not the first to detect some more or less regular periodicity in the pattern of crises and booms (Jevons, 1884: p. 129, cited publications by Hyde Clarke in 1847), the idea that trade and prices follow a cycle gained force in the 1860s with the empirical work of Clément Juglar (1862) and W. Stanley Jevons (1884) (a collection of his articles from 1862 to 1882 edited after Jevons' death by Herbert S. Foxwell, his successor at University College), with later writers from London School of Economics (LSE) director Sir William Beveridge to NBER founder Wesley Mitchell (1927) and Joseph Schumpeter (1939) going beyond a single cycle to interpret time series as several superimposed cycles of differing amplitude and periodicity. The literature was immense (O'Brien (1999), Hagemann (2001), Boianovsky (2005) offer 11 volumes of selections from the primary sources) and, following the establishment of Wesley Mitchell's NBER in the United States and the London and Cambridge Economic Service and the National Institute of Economic and Social Research in Britain, conjuncture or business cycle research institutes flourished in Vienna, Berlin, Kiel, Sofia, Warsaw, Moscow, and other European centers in the 1920s (the Austrian Institute for Business Cycle Research became the Austrian Institute for Economic Research after World War II).

Jevons' attribution of the 11-year trade cycle to the 11-year sunspot cycle, the periodic oscillation of solar activity, was responsible for economics being allowed to remain in the British Association for the Advancement of Science, by offering an apparently objective, scientific physical explanation for economic fluctuations, but in modern macroeconomics, the term 'sunspots' refers to any intrinsically irrelevant variable. Jevons' hypothesis, while mistaken, was not unreasonable: meteorologists of the time believed that sunspots affected the weather: cycles in rainfall and temperature would cause cycles in agricultural harvests, and agriculture accounted for a larger share of the world economy in the 1860s than it does now. When sunspots were believed to follow a cycle of 11.1 years, Jevons founds an 11-year cycle in prices, "and when the sun-spot cycle was revised to 10.45 years he was able to make the average interval between English crises 10.466 years" (Mitchell, 1927: p. 384). Jevons assumed that a cyclical effect must have a cyclical cause, but Frisch (1933) drew attention to Wicksell's remark that when a rocking horse is struck with a stick, the motion of the rocking horse does not resemble the motion of the stock. Seasonality, Jevons' other discovery of an economic cycle with a cyclical physical cause (also in Jevons, 1884), has fared better, and is the progenitor of seasonally adjusted time series.

With enough cycles, any time series could be 'explained' as the summation of cycles: using the periodogram (an early version of spectral analysis), Beveridge found 19 cycles in wheat prices with periods varying from 2.735 to 68 years (Dimand, 1999). In a paper first published in Russian in 1927 with an English summary, Eugen (or Evgenii) Slutsky (1937) used a moving average of the last three digits of the winning Moscow lottery numbers to demonstrate that summation and averaging of random series would produce apparent cycles where none existed. Slutsky (1937) and Ragnar Frisch (1933), and Fisher's critique of "the so-called 'business cycle'" as a "dance of the dollar," turned the attention of economists to oscillatory responses to external shocks (real or monetary), rather than underlying cycles (see Andvig, 1981 on Frisch and V. Barnett, 2011 on Slutsky). The Moscow Conjuncture Institute led by Nikolai Kondratiev, whose long wave theory implied that capitalism would experience another upswing after the Depression, was destroyed in Stalin's purges, with Slutsky retreating from economic topics to meteorology and statistics – ironically including research on sunspots (Kondratiev, 1997; V. Barnett, 1998, 2011). Other business cycle institutes survived but, as in the case of Mitchell's NBER, evolved into general economic research centers, with seasonality and leading indicators as the most specific lasting contributions of business cycle analysis. More generally, Christopher Sims' VAR approach to macroeconomics, starting with time series analysis without assuming much knowledge of the true underlying theoretical model, is in the spirit of the statistical approach to business cycle analysis undertaken by Juglar, Mitchell, Beveridge, and others.

Dynamics and Growth

David Ricardo, Thomas Robert Malthus, and John Stuart Mill analyzed the movement of profit rate, real wages, rent, and output as economies moved toward a stationary state in which the wage would equal the 'natural price of labor' and both population and the capital stock would be constant until the next innovation changed agricultural productivity (Hoselitz, 1960; Eltis, 1984; Hollander, 1997; Brewer, 2010). More formal algebraic modeling of economic growth began tentatively with Sismondi and then, drawing inspiration from Quesnay's *Tableau Économique*, more systematically with Karl Marx's schemes of simple and expanded reproduction in Volume II of *Capital* (Arthur and Reuten, 1998), which were developed further in debates between Rosa Luxemburg ([1913]1951) and Otto Bauer about whether the capitalist mode of production would inevitably break down after a certain number of periods because of insufficient purchasing power and sectoral imbalances (see Kalecki, 1967 and Joan Robinson's introduction to the 1951 translation of Luxemburg).

In his presidential address to Section F of the British Association, Allyn Young (1928), recently transplanted from Harvard to a chair at LSE, directed attention to Adam Smith's linkage of economic growth to increasing returns to scale ("the division of labour is limited by the extent of the market"), ironically just 2 years after Piero Sraffa had, in the same journal, shown that increasing returns are problematic for modeling equilibrium of the Marshallian firm. In the same journal issue as Young (1928), the Cambridge mathematician and philosopher Frank Ramsey (1928) analyzed optimal capital accumulation (with the first use of calculus of variations in an economics journal) in the first step toward what is now taught as the Ramsey–Cass–Koopmans model, and the same year G.A. Fel'dman (1928) attempted a formal model of capital intensity and output growth rates for Soviet central planning. But by 1930, Young and Ramsey were

dead (Ramsey at the age of 26), and Fel'dman had disappeared in Stalin's purges, and the lines of research they indicated were not pursued until much later.

From Cycles and Price Dynamics to Analysis of Aggregate Output and Employment

Although both monetary theorists and business cycle analysts were motivated by concern over periods of high unemployment (as well as by the social costs of rapid inflation, with Keynes' *Tract on Monetary Reform* and Fisher stressing the collapse of monetary exchange in the German hyperinflation of the early 1920s), they lacked a macroeconomic analysis of unemployment. Pigou (1913) talked about 'effective demand' in an early short book for the general public about unemployment, but his more formal and systematic *Theory of Unemployment* (1933) offered only a one-market analysis in which unemployment just meant that the wage rate was above the market clearing level. The implication of Pigou's analysis, which Pigou steadfastly refused to draw in his advice and writings on policy, was that wage cuts would eliminate unemployment even in the Great Depression. But Edwin Cannan did draw that conclusion in his 1932 presidential address to the Royal Economic Society (reprinted in Dimand, 2002: vol. III). Beveridge's *Unemployment, a Problem of Industry (1909 and 1930)* (1930), an expansion of his 1909 book, saw unemployment in search-theoretic terms, with labor exchanges as the means to more efficient matching of workers and jobs. Fisher (1933) presented a debt deflation theory of depressions, stressing the scramble for liquidity because of fears of default on inside debts with fixed money values, which later influenced Hyman Minsky (1975), James Tobin (1980), Ben Bernanke (2000), and Mervyn King, but at that time he had lost his audience by being so memorably wrong about the stock market. The mass unemployment of the early 1930s turned public attention from such academic authorities to underconsumptionists outside the mainstream (see Bleaney, 1976) or to Marxist claims that depressions and mass unemployment were inherent in capitalism. Schumpeter held that the Great Depression was just the regrettable coincidence of the troughs of three cycles of different lengths.

John Maynard Keynes, in his pamphlet *The Means to Prosperity* (1933b) and his 1933 Cambridge lectures (reconstructed in Rymes, 1989), and then more fully and formally in *The General Theory of Employment, Interest and Money* (1936), offered a solution to this impasse. Contrary to the Marxists, depressions and unemployment could be tamed without revolution or abolition of capitalism, by appropriate management of aggregate demand to offset fluctuations in expectations of the long-period profitability of new investment, fluctuations resulting from fundamental uncertainty about the future. Unlike John Hobson or other underconsumptionists, or Michal Kalecki writing in Polish within a Marxian tradition (Kalecki, 1967; translations of essays written in the 1930s), Keynes was a well-established figure within the profession, steeped in the Cambridge heritage of Marshallian monetary theory and saving-investment analysis (Eshag, 1963; Bridel, 1987; Laidler, 1999). Drawing on the multiplier analysis of his student Richard Kahn (1931), who together with Giblin (1930), Hawtrey (1932), and others had related changes in equilibrium income to changes in autonomous investment or exports (see Davis, 1980; Patinkin, 1982; Clarke, 1988; Dimand, 1988), Keynes (1933b, 1936) offered a theory of the equilibrium level of national income as the level of income at which desired investment equals desired saving. Noting that nominal wages had fallen by 30% in the United States in the early 1930s without reducing unemployment or real wages, Keynes (1936: Chapter 19) invoked dynamic arguments to deny that wage and price flexibility would guarantee restoration of full employment after a demand shock – sticky wages were his recommendation, not his assumption (see also Minsky, 1975; Tobin, 1980). Not only did Keynes have a message welcomed by policy makers and the public, but, combined with the creation of national income accounts and advances in econometric technique, his theory of the determination of aggregate income and employment provided an agenda for macroeconomists, drawing together the traditions of monetary theory and empirical studies of economic fluctuations. Regardless of later serious doubts by macroeconomists about the shift of emphasis from inflation to unemployment, or the eclipse of search-theoretic analysis of unemployment, or Keynes' sanguine view of the motivation of policy makers, the theory of equilibrium aggregate income and employment sketched in Keynes (1933b) and in his 1933 lectures (in Rymes 1989) and pamphlet and presented in the *General Theory* marked a transformation of a field that had a long and rich history by the time it acquired the name macroeconomics.

Macrosociology-Microsociology

Gianluca Manzo, GEMASS–CNRS and University Paris-Sorbonne, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by M. Cherkaoui, volume 13, pp. 9117–9122, © 2001, Elsevier Ltd.

Abstract

The history of sociology shows that the distinction between macro- and microsociology is at the same time fundamental and fundamentally ambiguous. This article presents a selective overview of the solutions to the micro/macro issue that have appeared in sociology from the classics to today's developments in philosophy of social sciences and sociology. The article aims to highlight the main sources of disagreement and division among sociologists interested in the micro/macro issue, and in the end stresses the importance of mechanism-based theorizing and formal methods to advance it.

Introduction

When the history of sociological theorizing has to be systematized, the distinction between micro- and macrosociology is fundamental (see, for instance, Collins, 1988; Cherkaoui, 2005: Chapter 5). But what are micro- and macrosociology? According to Randall Collins (1981: 984), "microsociology is the detailed analysis of what people do, say, and think in the actual flow of momentary experience. Macrosociology is the analysis of large-scale and long-term social processes, often treated as self-subsistent entities such as 'state,' 'organization,' 'class,' 'economy,' 'culture,' and 'society.'" While this broad characterization of micro- and macrosociology is largely undisputed (see for instance, Calhoun et al., 2012: 27), it seems problematic to provide a more precise definition. In fact, as noted by Münch and Smelser (1987: 356), "(…) the terms 'micro' and 'macro' have been assigned a number of diverse meanings in the sociological literature and these meanings are not always consistent with one another." Along similar lines, Wippler and Lindenberg (1987: 153) admitted that "there is no agreement on the micro/macro distinction, except that 'micro' always refers to smaller units than those implied by macro. (…) the various meanings attached to this distinction have generated micro/macro problems that stand in the way of an adequate solution of the master problem." Thus, the distinction between macro- and microsociology is at once fundamental and fundamentally ambiguous (as an additional proof, see Table 1 in Krause, 2013: 142).

In this short article, I first review solutions to the micro/macro issue that appeared in sociology from the classics to the 1980s. Without any claim to exhaustiveness, I select typical, in the sense of recurrent, solutions to suggest that (1) sociologists have often opted for a substantive understanding of the notions micro/macro, thus equating a given level of analysis with a given set of entities or phenomena; (2) sociologists have recurrently attempted to give one level explanatory priority over another; (3) in order to justify their 'priority' claims, sociologists have often mixed ontological and explanatory arguments (for an early statement along similar lines, see Wiley, 1988). In my opinion, these are the main sources from which the disagreements on the micro/macro issue arise. Then, by discussing in-progress epistemological, theoretical, and methodological developments, I suggest that such disagreements can be overcome provided sociology renounces the vertical, multilayer metaphor contained in the notions of micro and macro, and puts all its energy into the detailed description of the mechanisms that constantly transform small-scale heterogeneity into large-scale, time-resistant mixtures of homogenization and differentiation, whatever level the entities under study may be assigned on the low(micro) and high(macro) continuum.

Micro/Macro Balance

Although "the effort of classic sociology in no sense could be seen as having resolved the micro-macro polarization" (Alexander and Giesen, 1987: 19), the closest readers have recognized that classical sociologists were balanced micro/macro thinkers (Ritzer, 2008: 500). To see this quality, Boudon (1995) argued, one needs to inspect the complex interplay of programatic statements, methodological reflection, and empirical-oriented analysis in classical work.

Durkheim is a paradigmatic example. In the first chapter of *The Rules of Sociological Methods*, he defended the view that social structures have a reality in themselves, are external to individuals, and constrain their actions. By analogically building on biological and chemical phenomena like the 'hardness of bronze' or the 'liquidity of water,' Durkheim (1895 [1982]: 39) argued that the collective level arises from the individual one, yet the former is *sui generis*, meaning qualitatively different, from the later: "(…) the whole does not equal the sum of its parts; it is something different, whose properties differ from those displayed by the parts from which it is formed" (Durkheim, 1895[1982]: 128). That is why, according to some commentators (see Sawyer, 2005: Chapter 6), Durkheim should be regarded as the first 'emergentist' in sociology (on modern debates on the concept of emergence, see Bedau, 2003). However, as stressed, among others by Bearman (1991), Collins (2004: 32–40), and Cherkaoui (2005: Chapter 2, 2008: Chapters 1 and 3), this view did not restrain Durkheim from formulating detailed explanations in terms of networks, interactions, and actions of complex high-level outcomes like patterns of suicides or long-term dynamics of system differentiation.

Weber provides a specular case. In the foundational essay *Some Categories of Interpretive Sociology* (1913[1981]: 158), he

defined individuals as the 'atoms' of sociology and advised that sociology should start with individuals' actions and motivations and show how high-level structures and trends ultimately derive from them. However, similarly to Durkheim, Weber's analyses of specific social phenomena yield a more complex picture. For instance, Weber's study of the origin of capitalism as it is articulated in the *General Economic History* (1927[1981]) shows a complex explanatory model, which relates several levels of analysis and focuses on formulating specific hypotheses on mechanisms bridging these levels. Contrary to Coleman's (1987: 154–157, 1990: Chapter 1) criticism of Weber's analysis, which rests on commenting *The Protestant Ethics and The Spirit of Capitalism*, even the micro-to-macro step of Weber's explanation contained detailed analyses of relational and institutional factors that transformed individuals' beliefs into stable macrostructures – a point nicely illustrated by Cherkaoui (2005: Chapter 3).

Other classics pursued in practice this balance between micro- and macrosociology. Elster (1985, 2009), Cherkaoui (2005: Chapter 1), and Edling and Hedström (2009) have shown that, similar to Durkheim and Weber, Marx and Tocqueville were also attentive to the interplay between actions, interactions, organizations, and structures, and formulated specific hypotheses on detailed mechanisms relating several levels of analysis.

Micro/Macro Extremisms

The classical micro/macro balance was lost for a large part of twentieth-century sociology. As stressed by Ritzer (2008: 500), much modern sociological theory has been characterized by "micro and macro extremists – that is, the preeminence of theorists and theories that accord overwhelming power and significance to either the micro or the macro level." To capture this phenomenon, Turner (2001: 4) coined the polemic terms of 'micro-' and 'macrochauvinism.'

Talcott Parsons's structural functionalism played a crucial role in this radicalizing trend. Although in *The Structure of Social Action* (1937), Parsons's focus is on actors, the analytical importance of normative elements is already stressed without ambiguity. These elements will progressively become predominant with Parsons's *The Social System* (1951) and later work in which he studied how supraindividual structures are internalized by individuals and how these structures satisfy specific systemic needs. Parsons's (1954: Chapters 4, 15, and 19) writings on social stratification are exemplary of this approach. According to his interpretation, occupations crystallize different values, and the system provides larger symbolic and material gratifications to those occupations expressing the most important values at a given point in time. The specific (multilevel) mechanisms by which the consensus on these values emerges are left unspecified, however (for a detailed analysis of Parsons's work and more recent developments in 'system' theory, see, for instance, Joas and Knöbl, 2009: Chapters 2–4, 11, and 13).

As noted by Calhoun et al. (2012: 28), the most important 'microchauvinisms' grew in American sociology out of a reaction to Parsons's 'macroextremism.' On the utilitarian side, this is the case of Homans's (1961) defence of psychological reductionism and his project to deduce every supraindividual structure from more elementary forms of exchanges among self-oriented actors within small groups. On the interpretive side, although different when carefully inspected, ethnomethodology (Garfinkel, 1967), symbolic interactionism (Blumer, 1969), and Goffman's (1982) frame analysis share the assumption that supraindividual structures are transient and contingent, depending on the way actors interpret and negotiate the meanings of actions and situations when they interact -Schutz's (1937[1967]) social phenomenology being a power source of inspiration for these approaches.

Let us finally consider the interesting case of shifting from micro- to macroextremism within the work of the same author. Peter Blau is perhaps the most refined example of this trajectory in that he moved from a refined variant of social exchange theory (see Blau, 1964) to an equally sophisticated version of macroextremism focused on how population heterogeneity suffices to predict the patterns of social interactions (see Blau, 1977, and, for a summary, Blau, 1987, 2001).

Micro-Macro Linkage

Compared to this overemphasis on the micro- or the macro-level between the 1930s and the 1970s, sociological theorizing began to develop a more balanced perspective – closer to the spirit of classical empirically oriented analyses (see first section) – in the 1980s. In the introductory essay to *The Micro-Macro Link*, Alexander and Giesen (1987: 31) suggested that "(…) in the present decade a quite different phase of theoretical debate has emerged, one marked by the serious ongoing effort within every theoretical tradition and from both sides of the great divide to link micro- and macro-perspectives (…) we are convinced that the scope and intensity of this search for linkage are without precedent in the history of sociology." Münch and Smelser's (1987: 385) conclusion to the same book is equally explicit: "(…) those who have argued polemically that one level is more fundamental than the other (in some kind of zero-sum way), or who have argued for the complete independence of the two levels, must be regarded as in error."

The effort to reach a multilevel theorizing has been productive in different ways, however. In US sociology, some authors started with the idea that the distinction between micro- and macrolevels is too reductive to capture the complexity of social life. Thus, Alexander (1987) and Ritzer (2008: Figures 1–2 and A.1–3), for instance, suggested that we should instead think in terms of *continua* – in particular, the former proposes an individual/collective and an instrumental/normative *continuum* whereas the latter speaks of a micro/macroscopic and an objective/subjective *continuum*. By combining them, these authors argued, multidimensional analytical schemas can be built and used conceptually to map the variety of phenomena characterizing the social world at different levels of analysis. By contrast, other American sociologists still bet on the foundational value of a specific level of analysis to close the micro/macro gap. Randall Collins (1981, 2004), for instance, building on Durkheim and Goffman, suggested that a particular type of social interactions, i.e., ritual

interactions, that actors experience in a variety of social settings triggers emotions that in turn create a feeling of social belonging, which transforms microlevel disorder into macrolevel order. American students of social networks started with a similar assumption that the intermediate level of social relations is crucial to understand the micro-macro transition (see, for instance, Granovetter, 1973, 1983, 1985). Differently from Collins's qualitative perspective, however, network analysts did not limit themselves to a specific type of interactions. They started instead by empirically describing network-related features impacting on the kind of macrooutcome observed (for an example on the field of diffusion processes, see, for instance, Valente, 1995). Over the decades, social network analysts developed a well-specified set of mechanisms and theories on how microlevel entities and attributes translate into macropatterns (for an overview, see Borgatti and Lopez-Kidwell, 2011).

During 1980s, European sociology also developed original integrative approaches to the micro/macro issue. These approaches insisted on the circularity of 'structure' and 'action,' but they conceptualize this circularity in very different ways. On the one hand, Giddens's (1984) 'structuration theory' and Bourdieu's (1977, 1980[1990]) 'genetic structuralism,' although different in many respects, share the common assumption that there is a relation of codetermination between 'structure' and 'action.' In Giddens, this 'duality' is resolved by postulating that actors' practices dynamically create their own structural conditions, whereas, in Bourdieu, structures are assumed to become incorporated in actors through invisible socialization processes, so that structures silently reappear in the way actors behave and think. On the other hand, the 'structural-individualistic' approach developed by several Dutch sociologists (see Wippler, 1978; Wippler and Lindenberg, 1987) – or the very similar 'recursive' form of methodological individualism proposed by Boudon (1987) – starts with a specific image of actors, which assumes that actors have goals and attach subjective probabilities to different courses of action, and, instead of developing a general account of the relationship between structure and action, advises formulating specific 'bridge' hypotheses (i.e., hypotheses on the way structures impact on actors' goals and opportunities) and 'transformation rules' (i.e., hypotheses on specific institutions and processes that combine actors' action into collective outcomes).

Layered and 'Flat' Social Ontologies

As anticipated by the promoters of the micro/macro-linkage debate themselves (Alexander and Giesen, 1987: 31, 37), the set of solutions that took shape during the eighties did not lead to any widely accepted 'Newtonian synthesis.' In fact two opposite reactions can be detected. Both directly refer to ontology but develop opposite views.

Turner's (2005) reaction is a good example of the first perspective. His objection to both the 'multidimensional' and 'circular' approaches deserves to be quoted extensively: "the micro-macro distinction will not be theoretically resolved by talk about multidimensionality or recourse to tired old dichotomies like agency/structure, rational/nonrational, subjective-objective, action-order and so on. Instead, we need to be much more specific on the properties of the social universe that are denoted by the labels of micro and macro" (Turner, 2005: 407). Thus, according to Turner, to develop a truly multilevel sociological theory requires us to reject the idea that the distinction between micro and macro is purely analytical. One should accept instead that "these levels *are* reality" (Turner, 2005: 409). On this basis, Turner posits the existence of three levels – i.e., 'macro,' 'meso,' and 'micro' – each of which is characterized by specific entities, driven by specific forces, and described by specific lawlike regularities. The task of a truly multilevel sociological theory, Turner (2005: 417) argues, would be "to develop theoretical models and principles explaining the nature of the linkages across levels."

Thus, Turner's reaction to the US micro/macro debate and to the European agency/structure literature is in line with the so-called 'critical realist' perspective, which, as Gorski (2013: 659) puts it, "instead of a purely conventional distinction between 'micro' and 'macro' [it] appeals to the real ontological distinctions between the various layers or 'strata' in the natural and social worlds." Within this framework, the solution to the problem of the micro/macro linkage would come from postulating the existence of a series of levels of reality with 'emergent,' meaning irreducible, properties and seeking to discover the origin of such 'originality' at each level as well as the effects of higher levels on lower levels (what is called 'downward causation' in this perspective). Archer's (1995) 'morphogenetic' approach as well as, more recently, Sawyer's (2005: Chapter 10, in particular) 'emergentist' sociology represent two sophisticated examples of this line of thought.

An equally 'radical' but opposite solution to the problem of linking micro and macro claims that the problem can be advanced by giving up the notion of level itself. This is the option chosen by Latour (1999), for instance. In an attempt to clarify the meaning of his 'actor-network theory,' he states that (1) "(…) the social possesses the bizarre property of not being made of agency and structure at all, but rather of being a circulating entity"; (2) "(…) in the social domain there is no change of scale. It is so to speak flat and folded (…)"; (3) "(…) there is no zoom going from macro structure to micro interactions (…)" (Latour, 1999: 17, 18, 19, respectively). For this reason, 'action-network theory' suggests not thinking in terms of levels but in terms of 'circulations,' 'trajectory,' or 'movements.' A similar, although more sophisticated, position is endorsed by Abbott (2007). Within the context of a discussion on mechanism-based theorizing in sociology (see last section below), he claimed "(…) the Coleman Boat presupposes a whole model of levels that it is the task of my own version of social theory to destroy. There are no levels. The levels concept is incoherent, an uncriticized inheritance from liberal political theory" (Abbott, 2007: 2). As an alternative, he suggests a relational and processual perspective that pays attention to the 'fractal' nature of the social world (see Abbott, 2001: Chapter 6) – interestingly, this 'fractal' nature is something denied by Latour (1999: 18). At the same time, Abbott (2007: 2) honestly admits that we do not really have at the moment a 'serious' theory that allows us to think of the social world with level-free eyes.

Toward a Scale-Based Thinking

It is a fact that the integrative stage of the history of the micro/macro debate was not capable of generating shared solutions. The authors who explicitly characterized the micro/macro distinction in analytical terms and at the same time attempted to integrate several levels of analysis were attacked on several grounds. First, it was observed that some of them tend conceptually to map social reality more than theoretically articulate its dimensions (see Turner's (2005: 407) objection to Alexander's or Ritzer's proposals). Second, concepts like 'duality of structure' or 'habitus' were criticized for restating the problem of structure/agency codetermination instead of providing the details of the interplay between the two (see Ritzer, 2008: 526; Turner, 2005: 406–407; Van den Berg, 1998). Third, it was remarked that, despite the programatic claim, integrative approaches ultimately end up giving one level priority over another, so that, for instance, Collins and Bourdieu finally remain a 'microreductionist' and a 'macrostructuralist,' respectively (see Ritzer, 2008: 507–510, 532). On the other hand, social theorists who overtly proposed a multilayer ontology, thus opting for the notion of 'levels of reality' rather than that of 'level of analysis,' raise the difficult question of the determination of the number, the content, and the frontiers among these levels. A quick comparison of Turner's (2005: 410–411) Table 23.1 with Sawyer's (2005: 211) Figure 10.3, for instance, would suffice to show that these choices are arbitrary, a priori, and ad hoc. Without empirical research, lists of 'levels of reality' are nothing but lists of verbal labels. Unfortunately, and somehow surprisingly, a similar objection also applies to theorists who opted for an analytical understanding of the notion of level in that micro- and macrolevels tend to be in practice equated to specific entities and activities. This is undesirable for two reasons. First, different micro- and macroperspectives usually opt for different micro- and macrocontents, thus generating conceptual ambiguity and confusion. Second, as soon as a specific content is given a specific level, one risks shifting from an analytical to a substantive, ontological characterization of this level, which in turn increases the probability that the discussion will turn to what exists or not in the social world (on this danger, see, among philosophers of social science, Little, 2006).

Recent debates in philosophy of social science seem to open a fruitful avenue to a resolution of these problems. In particular, Ylikoski (2012, 2014) proposes articulating three elements, namely the concept of 'scale,' the distinction between 'constitutive' and 'causal' statements, and the concept of 'mechanism.'

As to the first element, Ylikoski suggests that the distinction between micro and macro could be better described in terms of small- and large-scale phenomena (Ylikoski, 2014: Section 3). To think in terms of scales, he argues, would help avoid the implicit level-based vertical metaphor contained in the notions of micro and macro. The notion of level raises indeed the difficult question of knowing in what sense a social norm, for instance, is a higher level entity than the individuals believing in it. After all, the social norm, to be effective, should reside in the minds of some individuals (at least those who enforce the norm or those who are in charge of having the norm enforced). Thus, in this sense, the norm would be on the same level as the individuals. Within the scale-based framework, this ambiguity disappears; the norm is at a different scale than the actor in that, to be a social norm, it must hold for more than one actor (otherwise, it would be a private normative belief). The difference in terms of level is thus replaced by simpler differences in terms of size. The notion of 'scale' also makes it clear that the distinction between micro and macro, thus between 'levels,' can only be relative and content-free in that it depends on the target one is seeking to describe/explain – if one focuses on individuals interacting within a triad, then transitivity is a large-scale property, but transitivity becomes a small-scale phenomenon when one starts studying the dynamics of interactions within a given firm.

In Ylikoski's argument, scale-based thinking should be combined with an appreciation of the difference between 'constitutive' and 'causal' statements (see Ylikoski, 2012: 2.4; 2014: Section 4). A constitutive statement, he remarks, establishes a relation of dependence between small- and large-scale properties whereas a 'causal' statement describes a relation of dependence between the events that are responsible for the transition between phenomena at different scales. The distinction, Ylikoski argues, is important because it helps avoid the conflation between ontological and explanatory statements. The fact that a given large-scale phenomenon is *made of* smaller scale entities (constitutive viewpoint) does not imply that, to explain the former, one only needs small-scale events. From the point of view of 'causal' statements, the 'difference-makers' are not limited to a single, unique scale.

Within a scale-based framework aimed at answering 'causal' questions, Ylikoski (2012: Sections 2.2 and 2.4.1) finally suggests, the fundamental problem of scientific knowledge becomes the discovery of the 'mechanisms' that transform small-scale properties into larger-scale patterns as well as the mechanisms that clarify the way large-scale properties impact on the activities of smaller scale units. Thus, the problem is no longer what the micro or the macro is, nor what the most fundamental level of analysis is. The problem of micro- and macrosociology is reshaped in more general terms, i.e., as an enterprise of figuring out the details that make the connection between phenomena located at different scales, whatever their specific content.

Recent developments in sociological theory suggest that these ideas are progressively traveling from philosophy of sciences to sociology, and transforming the way sociologists conceive the distinction between micro- and macrosociology. I close this article by reviewing these developments.

Mechanism-Based Thinking

The explicit use of the concept of mechanism, entered sociology in the 1990s (see Hedström and Swedberg, 1998; for an analysis of precursors, see Manzo, 2010: 132–138). Over the last two decades, a distinctive sociological perspective called analytical sociology was elaborated around this concept (see Hedström, 2005). Its foundational axiom is that to explain a connection between events amounts to detailing the set of entities, properties, activities, and

relations among them that brings about the observed connection. Analytical sociology is now a complex intellectual movement that orientates empirical research in several areas (see Hedström and Bearman, 2009; Manzo, 2014a) and stimulates interesting controversies (see Abbott, 2007; Little, 2012; Opp, 2013). Analytical sociology is deeply concerned with the micro/macro issue. In this respect, three elements of this research program must be briefly discussed: (1) the form of methodological individualism that animates analytical sociology; (2) its views on the theory of action; and (3) some of its methodological proposals (for a more general and detailed discussion, see Manzo, 2014b).

As to the first point, analytical sociology's view is deeply in line with the distinction between 'constitutive' and 'causal' statements discussed in the previous section. From a 'constitutive' point of view, large-scale properties are assumed to be *made of* smaller scale entities and properties. A network-related property like transitivity, for instance, must be constitutively explained by referring to some properties of smaller scale entities such as their tendency to associate with similar others. In this sense, analytical sociology is reductionist. However, from a causal explanatory point of view, analytical sociology acknowledges the empirical existence of large-scale properties and structures, which are defined in the following way: (1) once they come into existence, large-scale properties span a temporal window wider than that characterizing the small-scale entities that have dynamically contributed to generating them; (2) once they have come into existence, large-scale properties cannot be meaningfully defined, or quantified, for a single small-scale entity (on this second feature, see Hedström and Ylikoski, 2014: 62); and (3) the specific value and form assumed by large-scale properties crucially depends on the system of interdependencies that exist among the set of small-scale entities that have dynamically contributed to generating them. Analytical sociology not only acknowledges the empirical existence of large-scale properties and structures but also that they are causally relevant; the only requirement is that it should be possible to indicate at least one small-scale element through which the large-scale effect operates – when the small-scale entity is an actor, no matter whether consciously or unconsciously.

Thus, this understanding of the micro/macro relationship is compatible with the form of structural individualism originally formulated by Dutch sociologists and Boudon (see previous section) as well as with its dynamic version proposed by Coleman (1993: 63). However, to recast this doctrine in terms of scales and pay attention to the distinction between 'constitutive' and 'causal' statements avoids the undesirable misunderstanding that the micro must necessarily be equated with actors and their activities.

With respect to the second point, i.e., the theory of action followed by analytical sociology, two novelties must be highlighted. First, contrary to what some have argued (see, for instance, Gross, 2009), there is nothing in the spirit of analytical sociology that commits this perspective to a specific action theory. On the one hand, when intentionality and rationality are mobilized, it is an open understanding of rationality in terms of reason-based behavior that is assumed (see Manzo, 2010: 150–157, 2012). On the other hand, both the 'wide' and a fortiori, the narrow version(s) of rational choice are explicitly criticized for their lack of realism (see Manzo, 2013a; Hedström and Ylikoski, 2014). The second novelty concerns a trend within analytical sociology toward the recognition that individuals and their (intentional) actions should not necessarily be regarded as the basis of final explanation (see Hedström and Ylikoski, 2014). As stressed by Ylikoski (2012: Section 2.5), 'intentional fundamentalism' is unmotivated from the point of view of the mechanism-based account of explanation, which is neutral with respect to the rock bottom of causal chains. Thus, although analytical sociology echoes previous solutions to the micro/macro issue, namely within the rational-choice tradition (see, for instance, Coleman, 1987), analytical sociology differs by not committing to a specific theory of action, or to a specific level of analysis. This choice is likely to increase the domain of application of the perspective.

One aspect of analytical sociology's methodology, which is my third point, tends in the same direction. With the partial exception of the rational-choice tradition, which built its micro/macro theorizing in part on mathematical models (for a recent statement, see Raub et al., 2011), the perspectives reviewed in the previous sections relied either on natural language or on statistical methods whose internal structure makes it impossible to represent specific mechanisms bridging different levels of analysis (for an old statement, see Coleman, 1987: 168–171). This is especially true when 'transformation' mechanisms involving dynamic interdependencies are at stake (see Coleman, 1986: 1316). By contrast, analytical sociology proposes a particular simulation tool, i.e., agent-based modeling, in order to formalize multilevel mechanism-based hypotheses and study their consequences. Note that, among theorists involved in the micro/macro debate, the potential of simulation models did not go unnoticed (see, for instance, Collins, 1988: Appendix; Turner, 2005: 420). However, compared to other simulation techniques, the flexibility and power of agent-based modeling opens new and unhoped-for opportunities for micro/macro sociological theorizing. Let me briefly explain why (for a more detailed discussion, see Manzo, 2014b: 29–35).

Because of the algorithmic nature of the technique and the specific programing language used to write such algorithms, any substantive mechanism for which one has a theoretical representation can be implemented and studied within the framework of agent-based modeling. For sociologists interested in theorizing about transitions among levels of analysis, this flexibility is especially appreciable for the following reasons: (1) Despite their name, agent-based models are not at all limited to representing 'individuals.' According to the bundle of properties and rules that one programs for a given class of objects, the latter can be used to design the behavior and interactions of a set of particles, molecules, cells, beliefs, actors, groups (of particles, molecules, etc.), organizations, or whatever else on which one may have a precise theoretical understanding and representation. Thus, the specific way in which an 'object' is programed and the specific type of relations that the programmer establishes among different classes of 'objects'

allow representation of any form of connections and exchanges among entities located at different levels of analysis. (2) Agent-based modeling is entirely agnostic about the logic of action by which agents are driven. Thus, if the small-scale entities to be represented are individuals, then self-interested maximizing agents can be designed as well as more or less sophisticated 'cognitive' agents, or even agents that are driven simply by heuristics. (3) Agent-based modeling makes it possible to handle several forms of heterogeneity. Agents can be heterogeneous in terms of attributes and attributes' values. More radically, agents can be heterogeneous in terms of activities, tasks, or the behavior rules by which they are driven. The temporal order in which these rules are performed can also vary across agents. Thus, agent-based modeling constitutes a robust formal tool to go beyond the metaphor of the 'representative agent,' an unrealistic metaphor widely used to avoid, rather than to solve, the problem of the transition from the small- to the large-scale phenomenon (see Gallegati and Kirman, 1999). (4) Agent-based modeling makes it possible to design both space- and network-based local interactions. Agents can be embedded within these interactions so that their beliefs, desires, and opportunities can be modeled as locally constrained and influenced by the choices of other agents and by the network's topology. Moreover, compared to social network analysis, agent-based modeling makes it possible to turn network-level patterns such as homophily, triadic closures, cycles, balanced structures, structural holes, or brokerages into dynamic mechanisms, and their large-scale consequences can be studied (among students of social networks the interest of agent-based simulations is increasing indeed, see Monge and Contractor, 2003).

In a nutshell, agent-based modeling represents a flexible virtual laboratory in which the consequences of specific mechanisms connecting entities at different scales can be studied in a rigorous way. To build such artificial societies requires that every detail is specified. For micro/macro theorizing, this obligation has two advantages. First, conceptual vagueness cannot exist; second, when one takes shortcuts because detailed knowledge is not available, this limitation is immediately visible, thus helping to see where our theoretical knowledge must improve.

With respect to the micro/macro issue, what kind of theorizing can analytical sociology produce on these bases? Analytical sociology does not seek a 'grand' theory explicating how the connection between small- and large-scale phenomena works in general. Analytical sociology's ambition is to provide detailed descriptions of how this connection unfolds for specific and limited portions of the social world. In multiplying these local inquiries, the goal is to detect common features across contexts and phenomena so that classes of semigeneral, in the sense of transversal, mechanisms can be found (see Hedström and Bearman, 2009: 7). Examples of this approach can be seen in the effort to establish if network-based exposure mechanisms are equally involved in the emergence of large-scale suicide patterns (Bearman and Moody, 2004; Hedström et al., 2008), inequality structures (DiMaggio and Garip, 2011; Manzo, 2013b), fertility trends (Gonzalez-Bailon and Murphy, 2013), friendship dynamics (Bearman et al., 2004), or norm enforcement (Centola et al., 2005); if matching mechanisms work similarly on the job market (Stovel and Fountain, 2009) and for mate choices (Todd et al., 2005); or if imitation-based cumulative-advantage mechanisms apply to both the origin of status hierarchies (Gould, 2002) and consumption fads (Salganik and Watts, 2009).

This may seem not ambitious enough, but I believe it should help sociology to accumulate knowledge on how small-scale differentiation is turned into large-scale mixtures of differentiation and homogenization that is more precise than general transition modes – like 'aggregation,' 'combination,' 'externalization,' 'internalization,' or 'conformity' – which, according to some observers (see Münch and Smelser, 1987: 376–385), constitute the main outputs of several decades of micromacro theorizing.

Concluding Remarks

According to Archer's (1995) reconstruction, the solutions sociologist have proposed to the micro/macro, agency/structure issue historically fall within three types, i.e., 'downward conflation' (low-level entities are epiphenomenal compared to high-level entities), 'upward conflation' (high-level entities are epiphenomenal compared to low-level entities), and 'elision' or 'central conflation' (high- and low-level entities are inseparable and mutually constitutive). The sample of authors and perspectives overviewed in this article suggests that Archer's typology captures the fundamental trends of much of the debate. It is unsatisfactory, however, in three regards.

First, Archer's account does not consider heterodox readers who, contrasting usual interpretations, have shown that the classics are balanced micro/macro thinkers whose empirically oriented analyses escape Archer's three forms of reductionism. Second, Archer does not consider specific variants of the rational-choice tradition, modern social network analysis, and, for chronological reasons, the analytical sociology research program, all of which are approaches that reject both 'downward' and 'upward' conflation and seek to detail the mechanisms responsible for the interplay between structures and actors, thus avoiding 'central conflation' as well. Finally, again for chronological reasons, Archer's constructive proposal inspired by the critical-realism school of philosophy could not take into account recent epistemological developments that raise doubts about the utility of positing a priori an n-layer ontology, and suggest that, be it analytical or realist, the cake-layer model of society implicit in the level metaphor can be fruitfully replaced with a scale-based, flat perspective.

Thus, ultimately, this article suggests that the debates on the micro/macro issue are entering a new phase in which "there is no longer any demand for rigorous strategies of reduction" (Giesen, 1987: 337), and robust methods now exist for designing bridging mechanisms instead of only talking about them.

Abstract

Mafias develop in failing states. Such states often continue failing because of the very presence of mafias and their collusion with politicians and civil servants. This happened in western Sicily in the nineteenth and twentieth centuries with the development of a modern market economy that was left without protection and created a demand for alternative protection. Men skilled in the use of violence and loosely organized in autonomous, informal, local groups, called mafias, enforced alternative, nonstate ('criminal') protection. Following the abolition of feudalism and the confiscation of church domains, vast landed estates (latifundia) came up for sale. The reforms increased the number of absentee landlords and widened the gaps between them and the peasants left without compensation for the lost user rights on the estates. Mafiosi operated as powerbrokers between absentee landlords and a growing peasant proletariat. The expansion of the suffrage in the twentieth century reinforced existing power relations based on patronage. Once more, a democratic innovation favored mafia structures, organized as political machines to gather votes and keeping at bay a barely controlled class war. Mafia presence was particularly strong in western Sicily: in and around Palermo and in its vast and desolate hinterland of large cereal-pasture holdings and isolated agro-towns on hilltops that separated the peasants from the land. The near absence of mafia in the eastern part of Sicily coincides with a less colonial and a less 'feudal' past, resulting in a more equal distribution of land, more intensive and diversified cultivation patterns, an advanced infrastructure, and more democratic institutions, similar to areas in the northern parts of Italy.

Mafia

The term 'mafia' originates from western Sicily, in particular from Palermo – for long the capital of wealth and power, and also a city of great poverty among its vast proletariat – a main recruiting field of *malfattori* (evildoers). Mafia refers to enforced protection of property provided by local, informal, autonomous, loosely organized groups, called 'families,' *cosche* (plural of *cosca*), or simply 'mafias.' Each group choses its own leader (*capo*) and forms a confederation with other, similar groups without losing its autonomy. These brotherhoods are named after the territory they control and protect: a village, a town, an urban neighborhood. Mafias are essentially local: first and foremost they depend on local knowledge – not unlike anthropologists. The Sicilian mafia is a grassroot movement raised from the ranks of the desperate poor. Segmentation and democracy rather than hierarchy rule the complex world of mafia.

Because they are autonomous and do not recognize any superior power, mafias are sovereign and resemble states, as sociologist and historian Charles Tilly explains in an influential essay, "War making and state making as organized crime" ([1985]1997). As a local group, a mafia polices a territory, provides protection, settles disputes, extracts a tribute, and wages wars with other *cosche*. All these functions are interrelated and influence each other. Mafias interact in conflict and accommodation, form alliances and coalitions, and engage in bloody wars, but leave their own members free to cultivate and maintain relations with outsiders and develop their own network of 'friends' across class and place, most notably politicians. Although lacking an effective centralizing ruling body, the Sicilian mafia, like mafias elsewhere, is a unitary social, cultural, and political confederation, called '*Cosa Nostra*' ('Our Thing'). Major local chiefs are represented in a commission that has mainly coordinating tasks (Gambetta, 1993; Paoli, 2003.) The so-called '*apo di tutti capo*' is a local chief whose influence reaches beyond his own *cosca* but usually respects the autonomy of other local mafias. This also holds for the most famous ones, including Vito Cascio Ferro (1862–1943), Calogero Vizzini (1877–1954), Giuseppe Genco Russo (1893–1976), Salvatore Riina (1930), and Bernardo Provenzano (1933). Tellingly, they all came from humble families in small towns located in the latifondo area of Sicily's western interior, Bisacquino, Villalba, Mussomeli, and Corleone, respectively.

Whatever its feudal aspects, mafia is a modern phenomenon and has developed with the advance of an expanding market economy in a context where the state failed to protect property rights and settle disputes (Gambetta, 1993; Varese, 2006, 2012). Following the abolition of feudalism in 1812 and the subsequent confiscation of church domains in the early 1860s, shortly after the unification of Italy in 1861, vast landed estates came up for sale. These reforms left large sections of a booming market unprotected which created a demand for alternative ('criminal') protection, to which men skilled in the use of violence responded. They included former estate guards, bandits, outlaws, ex-soldiers, and ambitious, ruthless peasants and shepherds recruited from the poorest sections of the rural population. To make things worse for the working classes, the new state imposed taxation, conscription, and obligatory education, which further alienated them from the new government. Schools withdrew their children from the family's labor force and were, therefore, considered an imposition. As a consequence illiteracy rates remained high far into the twentieth century. Prospective conscripts fled to the mountains and formed or joined armed bands, making banditry endemic in large parts of Sicily's interior parts for decades after unification. The army fought pitched battles with assorted robber bands at the cost of human life on both sides and the loss of

natural resources as forests were cut down or set on fire to combat outlawry (Mack Smith, 1968: 445–479; Fiume, 1984; D'Alessandro, 1959).

The transition to a modern market economy deprived most peasants from any compensation for their lost user rights (*usi civici*) on former feudal and ecclesiastical domains that were essential for their survival. (Blok, 1974: 37–42). The market economy widened the already considerable gap between landowners and peasants. Throughout the nineteenth century, proletarization of the workforce and rural poverty encouraged theft and organized banditry, an abortive peasant movement in the early 1890s, and subsequent massive emigration to America (Fiume, 1984; D'Alessandro, 1959; Romano, 1959; Blok, 1974). In the absence of reliable central control over the means of violence, mafia took shape as an *instrumentum regni* of Italian politicians, who chose to rule Sicily through its dominant agrarian classes – the absentee urban aristocracy and an upwardly mobile rural bourgeoisie. The expansion of the suffrage to all males – another democratic innovation – reinforced the existing power relations based on networks of patron–client relationships, in Sicily called 'friends-of-friends.' At the local polls, mafiosi canvased more votes for their representatives in parliament. "Mafia *cosche*," noted the Sicilian political scientists Gaetano Mosca at the beginning of the twentieth century, "immediately understood the great advantage that they could draw from participation in the political and administrative elections. This participation became more effective and active after the law widened the suffrage and gave the right to vote to the members of the *cosche* and to the classes in which they had greater influence and enjoyed prestige" ([1900]1949: 243, cited in Paoli, 2003: 186–187). Explains Paoli: "The clienteles organized by the *capimafia* – their nuclei formed by mafia groups – mingled with a wider network of clientelistic relationships through which the central government integrated southern upper classes into the national political system and secured their support for liberal government majorities" (2003: 187). With the further extension of the suffrage and the rise of the Popular and Socialist parties, prime minister Giovanni Giolitti (between 1903 and 1915) favored the strengthening of mafia structures, organized as political machines to gather votes for liberal clienteles and notables – and promoted their legitimation. "The action of mafia clienteles was, in fact, openly supported by state authorities at all levels, including even the prefects – the direct representatives of the central government in the single provinces" (Paoli, 2003: 187).

This aspect of the Sicilian mafia – its 'contiguity,' its 'cohabitation,' its collusion, its interweaving with state authorities, which helps accounts for its reproduction – gets somewhat lost in the revised perspective that emphasizes "mafia as a perverse response to modernization and the emergence of a market economy in a context where the state failed to protect property rights and a supply of individuals trained in the use of violence was available to offer alternative, nonstate enforcement" (Varese, 2006: 411–413).

Mafia presence was particularly strong in and around Palermo, in the adjacent citrus fruit areas of the *Conca d'Oro* (Golden Shell) and in its vast and forbidden hinterland of the island's western interior (Lupo, 1996: 103–147; Schneider and Schneider, 1976: 19–40). This was the area of large cereal-pasture holdings (the so-called *latifondi* or *ex-feudi*, whose history goes back to Antiquity) with its agro-towns situated on hilltops and mountain slopes for reasons of safety, but paradoxically alienating the peasants from the land and creating insecurity in the countryside. On a desolate, rolling, and mountainous landscape with huge stretches of wheat fields and pastures, large herds of sheep and cattle were driven from pasture to pasture according to the season. The arrangements facilitated one of Sicily's major 'industries' called *l'abigeato*, large-scale cattle rustling. Transporting the animals over long distances required the cooperation of various accomplices, including members of local *cosche* (Fentress, 2000: 132–133; Schneider and Schneider, 2003: 24–25). Cattle rustling in Sicily's western interior throws light on mafia's origin and class – and helps understand its continual reproduction, a point *pentito* (justice collaborator) Vincenzo Marsala made when talking to judge and prosecutor Giovanni Falcone: "… if you don't start with the rural towns, you will never uproot this noxious weed. The hinterland [of Palermo] is the great reservoir of manpower for the mafia, allowing it to continually find fresh blood for its membership" (cited in Stille, 1996: 191).

In this world of large-landed estates in Sicily's western interior, absentee landlords entrusted the management of their properties to ambitious, unscrupulous, upwardly mobile leaseholders (*gabellotti*) and overseers who had a reputation for violence. Until the advent of land reform in the 1950s, land was subleased to peasants on short-term contracts. These local bosses and their retainers formed the backbone of the rural mafia. The typical mafioso was a mediator or power-broker, who thrived on the gaps in communication between landlord and peasant, seller and buyer of commodities, political candidate and electorate, and exchanging services and 'favors' with his clients. Ultimately, he held sway over the links between state and local communities.

The earliest reference to what only much later would be called 'mafia,' comes from a report of a Neapolitan magistrate, the general prosecutor in Trapani, a major town in western Sicily, who in 1838 wrote to the Minister of Justice in Naples, well before the term 'mafia' appeared in print in the mid-1860s:

"In many towns and villages [in Sicily] there are fraternities, sort of sects that are called '*partiti*' without meetings and without other links than those of dependency on a chief who is here a landowner and there an archpriest. Common funds serve to meet certain ends as, for example, to exonerate a civil servant or to accuse an innocent person …. The population colludes with convicts. When thefts take place, mediators emerge and offer their services to make up for the stolen goods …. Many high-placed magistrates cover up these fraternities with an impenetrable shield …. It is impossible to induce the town guards to scout the area, nor is it possible to find witnesses of crimes committed in full daylight. At the top of this state of dissolution is the capital [Palermo] a city in which live 40,000 proletarians whose subsistence depends on the pomp and caprices of the rich and the powerful" (cited in Marino, 1964: 56). The reader may note that Biundi's *Vocabolaria Siciliano-Italiano* (Palermo, 1851) does not have entries on 'mafia' and 'mafioso.' The etymology of 'mafia' is controversial. See Novacco (1959) and Gambetta (1993: 135–140, 259–261).

This description contains all the elements of what mafia, after more than a century and a half, still stands for: informal, loosely structured, secret local sodalities ('fraternities') that police and protect a distinct territory, mutual aid, refusal to testify, and collusion with formal authorities, later called *intreccio* (Fentress, 2000: 147–181; Schneider and Schneider, 2003: 18, 33–34).

With the state's crackdown on the Sicilian mafia in the 1960s through the 1990s much more has become known about the subject through the reports from the Parliamentary Antimafia Commission and the detailed testimonies of several *pentiti* (ex-mafiosi who turned state evidence) in the maxi-trials in Palermo in the 1980s (Arlacchi, 1993, 1994; Gambetta, 1993; Stille, 1995; Jamieson, 2000; Schneider and Schneider, 2003; Paoli, 2003, 2008).

Local mafias impose a status contract on their members which involves a ritual initiation into the group and the adoption of a new identity of 'man of honor.' Having sworn an oath, members are obliged to keep secret their new identity as well as the composition, action, and strategies of their group. Their duty of silence is absolute. As in other secret societies, secrecy is a defense strategy (Paoli, 2003: 16–18; cf Simmel, [1908]1950: 346). Criminalized by the state as *malfattori*, *delinquenti* since the 1860s, mafia groups had to protect themselves from arrest and criminal prosecution for their continuous recourse to violence and had to resort to secrecy (Paoli, 2003: 17–18). Moreover, as Paoli explains, the initiation ceremonies of affiliation additionally created ritual ties of brotherhood among the members of a mafia family: the status contract is also an act of fraternization. The new recruits become 'brothers' to all members and share what anthropologists call a "regime of [generalized] reciprocity": this presupposes altruistic behavior without expecting any short-term reward. Paoli refers to an earlier account of a chief prosecutor, Lestingi (1884), who points out that mafia groups constitute brotherhoods whose 'essential character' lies in 'mutual aid without limits and without measure, even in crime' (cited in Paoli, 2003: 17). Paoli also recognizes that as secret brotherhoods using violence, southern Italian mafia federations (including the 'Ndrangheta' in Calabria) show striking similarities to organizations like the Yakusa in Japan and the Triads in China, Thailand, and Taiwan. These federations are also multifunctional (Paoli, 2008: 17–18; Varese, 2006: 411, 2012: 5, 17, 33, 147, 150–153). In his famous fieldwork study of Sicily, undertaken fifteen years after Italian unification, Franchetti already pointed at the 'extraordinary elasticity' of the Sicilian associations of *malfattori* (evildoers): "the goals multiply, the field action widens, without the need to multiply the statutes; the association divides for certain goals, remains united for others" (Franchetti ([1876]1993: 100; cited in Paoli, 2008: 18).

Yet this very elasticity may also question the brotherhood ideology and practice in mafias. The necessity of swearing secret oaths, common in secret societies as shown in La Fontaine comparative study (1985), may also betray a deep mutual suspicion among the affiliated. In his early essay on secret societies, Simmel pointed at their weaknesses. Secrets cannot be continuously protected. The protection it offers, notes Simmel, is indeed absolute, but only temporary: "a secret known by two persons is no longer a secret" (Simmel [1908] 1950: 346).

The vast volume of intra-mafia violence attests to this principle. Unintentionally, infighting exposes the very existence of mafias – about the last thing their members are waiting for. Moreover, violence is not restricted to wars between local mafias; bloody fights also occur between factions in the local *cosca* itself. Overweening leaders may invite resentment and several of them have been brutally killed and replaced by their former protégés. This happened, for example, in Corleone in the late 1950s when the much younger and ambitious Luciano Leggio killed his influential former boss Navarra, who had first tried to have him eliminated but failed. The altercation pertained to conflicting major economic interests (Chilanti and Farinella, 1964: 41–58; Catanzaro, 1988: 198–208). About 20 years later, a coalition of mafiosi from Corleone and Catania had the chief of the latter city's *cosca* murdered in an underhanded fashion. The victim harbored different views about the composition and policy of the Commission of *Cosa Nostra*. He was killed and replaced by his former protégé, Benedetto Santapaolo. Referring to the event, Antonino Calderone, the younger brother of the victim, later acknowledged – as a *pentito*, in a long and fascinating exposé – that everything in mafia comes down to sheer power. As Stille, referring to this case, phrased it, "[In] the simple code of the brutal, ancient world of the Sicilian countryside where force is the only law, there is no contradiction between personal kindness and extreme ferocity" (Stille, 1995: 231[228–234]; Arlacchi, 1993).

In their sober comments on current representations of the role of *cosche* and the 'coordinating' Commission, the Schneiders phrase the complexities as follows: "The prototypical nucleus of Sicilian organized crime consists of loose, at times shifting coalitions between leading mafiosi (select *capi*) and corrupt elites (regional and national politicians, administrators, professionals, and business men) engaged in the accumulation of power and wealth – not the overly conjured *cosca* or Commission" (Schneider and Schneider, 2003: 48).

Rather than a 'state-within-a-state,' as the Sicilian mafia has often been represented, mafiosi successfully infiltrated public institutions, including political parties, the judiciary, banks, and legal firms. They did so through their own personal network of friends rather than as members of sodalities or through the Commission. With the extensions of the suffrage in the course of the twentieth century, mafiosi enlarged their grip on the electorate and controlled more votes. Postwar government programs to 'develop' the country's southern periphery, enabled mafiosi to swallow up even more funds particularly in the (urban) construction industry. Writes Paoli, "From the 1950s onwards, Cosa Nostra groups, and later 'Ndrangheta families as well, set up their own building companies and pressed claims to become directly involved in both small and large building sites. Since 1980s, moreover, mafia enterprises of both regions [Sicily and Calabria] have become eager to obtain a share of any public work tendered by national or local public administrations. …. Unlike other western forms of organized crime, the meaning (and danger) of the two main Sicilian and Calabrian mafia organizations cannot be limited to their involvement in illegal markets. Their peculiarity lies in their will to exercise political power and their interest in exercising sovereign control over the people in their communities" (Paoli, 2008: 20–21). This last point is confirmed by the continuous

enforcement of a tribute, the so-called *pizzo*, all shops and business had to pay for protection to the local *cosca*. For a while, starting in 2004, and as part of the broader anti-mafia movement, another popular anti-mafia campaign in Palermo called ('*Addio Pizzo*') tried to evade this imposition by encouraging co-citizens to buy only in shops that refused to pay protection money to the local mafia. They did so under the slogan, "Pago a chi non paga" (I pay those who do not pay).

The Sicilian mafia is a form of organized crime, but not all forms of organized crime are mafias. As Varese convincingly argues, "the study of the mafia cannot be separated from the study of state failures" (2006: 441). If states fail, mafias can provide alternative protection of property and effectively settle business disputes. Although enforced and 'criminal,' mafia protection is not the same as extortion. It can even protect its clients against extortion. Also states enforce their protection on their subjects (2006: 412; Tilly, 1997). Yet Varese considers mafia protection a 'social evil.' He mentions several reasons: "In the economic sphere, it promotes inefficiency and reduces competition. By protecting thieves and other criminals, it also promotes further crime. The mafia operates without consideration for justice, fairness, or the wellbeing of society at large. In the world run by the mafia, there is no such thing as a 'right' to the protection for which one had paid. Mafiosi can ask for more favors or more money and then turn against their dutifully paying clients, and there is no higher authority to which a mafia victim can appeal" (Varese, 2006: 412–413).

Moreover, blaming the government of its neglect and theft (as in the common phrase '*Governo ladro*') obscures the reciprocal relation between condition and effect. Government investments (construction of roads and providing other public services) remain abortive as a result of the very practices of patronage, friendship, and self-help. Sicilians remain caught in a vicious circle of clientelistic politics and economic stagnation. As two anthropologists point out, "What clients ask from their patrons is not economic development but personal material advantages …. Clientelism entails not just the exchange of material favors or votes, but also the exchange of those products of the public administration (permits, licences, authorizations), which do not cost the patron money, but have a significant economic impact on the clients …. Highways may be built not because of their potential effect on economic growth, but because their construction creates numerous occasions for clientelistic exchanges" (Chubb, 1882: 3–6; Piattoni, 1998: 233–234). As mentioned above, the interweaving of political, economic, and mafia interests is called '*intreccio*,' or collusion (Schneider and Schneider, 2003: 18, 32–35). Next to class and culture, collusion is one of the factors that help account for mafia's longevity and reproduction.

Reciprocity between mafiosi and their clients is a form of lopsided friendship – a hallmark of patron–client relationships (Pitt-Rivers, [1954]1971: 140). In this generalized form of reciprocity, however, it happens that the mafioso will tell his client only later how, what, and where to reciprocate for a rendered service or 'favor.' In such cases, the client is tied up ('*vincolato*') and has to meet his obligation ('*levare l'obbligo*') whatever and whenever told. The mafioso can hold his client at a loose end, as a hostage of sorts, and as long as it suits him. This comes down to what more than anything else counts for mafiosi: showing power over other people. Mafia power is often sheer *prepotenza*; that is, showing that you are more powerful than others – and, for that reason, also more *omu* (man). It is an ultimate form of *abilità*, or self-help, in a failing state. Early German anthropologists neatly captured the conditions of *Selbsthilfe*, saying it looms large whenever the individual threatens 'to be either suffocated or be abandoned by the state' (Steinmetz, 1931: 522; cf Hess, 1970).

One may agree with Varese's view on mafia as a social evil – as simply organized crime. Yet other aspects deserve attention. The mafia developed, as noted above, as a reaction to extreme social injustice, humiliation, disrespect, and exploitation of the working classes. Its organization in brotherhoods in nineteenth and twentieth century western Sicily offered a respectable way out in the form of becoming 'men of honor.' As *pentito* Francesco Marino Mannoia explained to Palermitan Prosecutor Roberto Scarpinato, "Many believe that you enter *Cosa Nostra* for money. This is only part of the truth. Do you know why I entered *Cosa Nostra*? Because before in Palermo I was Mr. Nobody. Afterwards, wherever I went, heads lowered. And this for me was worth any price" (cited in Paoli, 2003: 152). Moreover, as results from prolonged local observation and participation in two rural communities in western Sicily (Blok, 1974; Schneider and Schneider, 1976), one should acknowledge the importance of long-standing, multi-stranded relations between local mafiosi and their clients, including ties of kinship, friendship, marriage, ritual kinship, and patronage which involves reciprocity of services and favors over time (cf Wolf, 1966: 81–91, 2001: 166–183). This brings us to the issue of mafia and Sicilian cultural codes – to the norms and values mafiosi share with other Sicilians. Here we touch on the breeding ground of mafia and its reproduction.

Although mafiosi exacerbated class tensions between landlords and peasants by their rent-capitalist management of landed estates and appropriating land and became landowners in their own right, they also controlled these tensions by carving out channels of upward social mobility for ambitious and ruthless peasants and shepherds. When indicted for violent crimes, mafiosi were usually acquitted for lack of evidence because of high-level protection while local witnesses would hesitate to testify against them (a favor the perpetrators would certainly not forget), which greatly helped to enhance their power and reputation of 'men of respect.' Inspired by both fear and admiration, the local population drew up a 'wall of silence' (*omertà*), which ultimately blocked effective prosecution of mafiosi and enhanced their reputation.

Sicilians may have mixed feelings about mafiosi (who remained somewhat ambiguous figures), but they can nonetheless strongly identify with them (Hess, 1970: 72–81). As 'men of honor' they have made themselves socially respected. More importantly, they show in their entire habitus the main cultural values and norms of Sicilian popular culture, including *omertà* (from *omu*, man), *abilità*, *furbería* (cunning, recalling the *metis* of Odysseus), care of family, conjugal loyalty, virginity of unmarried daughters and sisters, friendship, avoiding persons who represent the law, and ruthless ways when dealing with offences (*vendetta*). We find these cultural codes back and expressed in everyday practices

and situations, and further clarified in the use of numerous old yet current expressions, sayings, and proverbs (Blok, 2010). Following helpful suggestions of Sicilian historian Giovanna Fiume (1989: 203–205), a few examples suggest (without the intention to criminalize an entire population) to what extent mafiosi share these cultural codes that are widely accepted in western Sicilian society.

When confronted with (a picture of) the body of a murdered person, people may take a close look and identify categorically with the perpetrator, not with the victim, and comment with the standard phrase, "If he is killed in this (brutal) way, he must have done something terrible." In a world of failing states, *vendetta* is not only accepted but also encouraged as a social necessity – if only to ward off further violence. In similar cases people may also say, "*Bisogna pensare al vivo*." In translation, "One has to take care of the living one" – the perpetrator. An anecdote may further illustrate this point. When Marco Minghetti was the prime minister of Italy (1873–76), he made a trip to Sicily and visited the small town of Camporeale, situated west of the now well-known town of Corleone. The local priest introduced himself to him as follows: "I recommend to you a poor young man who needs your protection." Minghetti asked, "And why? What does he want?" The priest answered, "Nothing, he only met with an accident, he has killed a man" (cited in Alongi, 1891: 50). The exchange between the highest authority of the state and a local authority, familiar with indigenous customs and using the word '*poveretto*' (not only 'poor,' but also 'unfortunate') for a man who from the point of view of formal law was a criminal, involves a switching of codes still current today.

The values attached to *omertà* show how mafia practices and cultural codes dovetail with Sicilian popular culture at large. As the Schneiders explain: "Mafiosi adapted to expanding state power not only through the organizational arrangements associated with the *cosca* but also by actively and self-consciously manipulating the cultural codes of western Sicily, exploiting them as ideology. In this way, they were able to promote solidarity among themselves and at the same time to influence the attitudes and behavior of others (especially those who might testify against them in court). It made sense for mafiosi to become specialists in honor, friendship, and *furbería* (shrewd and cunning). Those codes were part of the local lexicon of many people; they symbolized the island's distinctive qualities vis-à-vis northern Italy and the rest of Europe; and they were instrumental in competition for power" (Schneider and Schneider, 1976: 192).

Above all, *omertà* comes down to be silent, pretending not to know, avoiding asking or answering questions. As the proverb indicates: "*Cu è surdu, orbu e tace, campa cent'anni 'mpace*". ("Anyone who is deaf, blind, and does not talk, will live a hundred years in peace" (Pitrè, 1978: III, 215–234)). This widely used proverb neatly captures the purport of the cultural code of *omertà* and refers to a habitus of reserve, secrecy, and reticence. Ex-mafioso and *pentito*, Tommaso Buscetta epitomized this world as "una cultura di tipo omertoso" (cited in Arlacchi, 1994: 84).

In Sicily people make much of friendship, but are no less aware of its dark sides. This awareness takes form in another cultural code and finds expression in several sayings. "*Amicizia con tutti, confidenza a nessuno*" ("Friends with everyone, trust nobody"). First, friends know much more about you than anybody else and do not raise suspicion immediately. For the same reason they may be the ones to (be asked to) turn against you. This also happened among "friends-of-friends." Intra-mafia killings – especially during the so-called mafia wars in the early 1960s and the period between the late 1970s and early 1990s – surpass homicides involving outsiders. Many victims were executed under the veil of friendship and hospitality, including betrayals within betrayals (Stille, 1995). The standard phrase "*Dagli amici mi guarda Iddio*" ("God protect me from my friends") implies that one can take care of his enemies himself. A friend of a prospective victim can be mobilized to carry out a killing, assist in it, or unknowably become an accomplice – if only not to raise the alarm of the victim. When the bandit Salvatore Giuliano (1922–50) had outlived his usefulness for politicians, he was, through mediation of local mafiosi, betrayed and killed by his closest ally, Gaspare Pisciotta, who was also his cousin (Maxwell, 1957). Tommaso Buscetta, a major figure in the mafia of Palermo who later moved to South America and had seen a lot of intra-mafia violence both in prison and on the streets of Palermo, referred to the ambiguities of friendship among mafiosi in an interview when detained as a *pentito* as follows. "The man who stands besides you might take you to your grave as easily as to a party. The dearest friend may become your murderer" (Arlacchi, 1994: 155).

From the late 1970s onward, mafia in Sicily gradually lost its role as a pragmatic extension of the State and assumed the character of a hidden power. Mafiosi disappeared as public figures with public identities. Mafia's peaceful coexistence with the State (the *pax mafiosa*) came to an end with the killing of politicians, policemen, magistrates, and numerous other civil servants, not to mention later terroristic attacks in three north Italian cities in the early 1990s. Terror replaced accommodation. Like outlaws elsewhere, mafiosi had to hide from the law (if they did not cooperate as *pentiti* with the judicial authorities), living clandestine lives as fugitives and outlaws in modest accommodations, mostly in their own territories. Several factors are responsible for this major transition.

First, beginning in the late 1960s, Sicilian mafiosi moved into the international narcotic trade, which produced huge and fast profits but entailed high risks. These ventures, like the building boom earlier, resulted in internecine struggles between rival factions. In this case between upstarts from the Palermo hinterland, like the Corleonesi, first led by Luciano Leggio and later by Salvatore Riina, and Bernardo Provenzano – the "viddani" (i.e., peasants: a contemptuous reference to their humble background), on the one hand, and the urban, rich, and chic establishments in and around Palermo of which Stefano Bontade was the most striking figure and close ('*intimo*') to Salvo Lima, the main Sicilian political patron, or *favoreggiatore*, who mediated between the majority government party (Christen Democrats, in power since 1948) and the mafia (Schneider and Schneider, 2003: 33, 55–57). The sustained, effective anti-mafia policies provoked campaigns of terror against politicians and civil servants as well as against family members of *pentiti*. This new development brought mafiosi into open conflict with the Italian State, which could not stand back and close its eyes to

the massive infiltration of drug money into its economy. Nor could the government ignore the pressure from neighboring States and other countries to take a strong position against the drug-trafficking and money laundering. The narcotics trade changed the Sicilian and American mafia. Although it became the mafia's most lucrative enterprise (at least for a while), it has also generated more murder, violence, and betrayal than any other criminal activity. As the profits spiraled, so did the need to protect them (Shawcross and Young, 1987: 307).

The extent to which the tables had been turned on politicians who had either directly or indirectly protected the interests of mafiosi for decades in exchange for electoral support can best be illustrated by the following incident. After the first Sicilian politicians and magistrates who tried to withdraw from the mafia or to combat it with determination were assassinated in public places in 1979 and 1980 to be remembered as the first wave of 'excellent cadavers,' Stefano Bontade, the flamboyant mafia leader in Palermo, allegedly warned the prime minister Giulio Andreotti on his visit to the island in February 1980 with the following words: "We're in charge here in Sicily and if you don't want to destroy the DC [Christian Democrats] you will do what we say. Otherwise we will take away our votes not just here but … in the whole of southern Italy. Then you will be left with only the vote in the North, where everyone votes Communist" (deposition of Marino Mannoia in the American witness protection program, as Stille clarifies, "Although Marino Mannoia did not participate in the private discussions, his boss, Stefano Bontade, later described the contents of the meeting to him …."; "Marino Mannoia provided the first eyewitness testimony tying Andreotti to the bosses of the mafia" (Stille, 1995: 391)).

The new generation of magistrates was helped by special legislation, which included a law that made it illegal to belong to the mafia (now defined as a criminal organization: '*associazione mafiosa*') and also gave prosecutors the power to seize mafia assets accumulated through criminal activity. From the early 1980s onward, the Italian State renewed its fight against the mafia, which culminated in effective proceedings (the so-called maxi-trials) against hundreds of mafiosi. The prosecution was substantially helped by mafiosi from losing factions who, partly for reason of revenge and partly in order to survive, repented, turned state's evidence, and helped build a case against their former peers (Stille, 1995; Jamieson, 2000; Schneider and Schneider, 2003).

Behind all these changes lurked an even larger transition. This was the demise of communism in Europe, which unintentionally undermined the mafia's *raison d'etre*. Since the immediate postwar years, mafiosi had always supported political parties that opposed communist and socialist parties. Faced with the strongest communist party in Western Europe, the Italian Christian Democrats could not forego the support of an informal power that provided huge blocks of votes and, thus, effectively staved off what was perceived as 'the danger of communism.' With the disintegration of the Soviet Union and the end of the Cold War, the situation radically changed and the shield of protection that for decades had kept mafiosi out of prison began to fall apart. The situation resembled the crackdown on the mafia under Fascism. Prefect Mori's large-scale operation in the late 1920s took place after the Sicilian landed classes had obtained more effective and less costly protection of their property from the new government.

This turn exposed mafiosi and left them without protection. Those who did not manage to emigrate were rounded up, tried, and convicted (Mori, 1933; Duggan, 1989). The fall of Fascism, the Allied occupation of Sicily, and the reestablishment of democracy in the 1940s created the conditions for a return and rebirth of the mafia as an *instrumentum regni* for politicians set to prevent the advent of a communist government in Italy, a country situated on the borders of Soviet influence.

Today, in the Italian pubic debate, the Sicilian mafia is still portrayed as powerful, almost invincible. Few observers express less pessimistic views and are, therefore, criticized by anti-mafia activists, who even accuse them of indirectly serving mafia interests. Still others believe that the anti-mafia fight has slowed down over the past few years (Paoli, 2008: 15). Paoli, who documents the current crisis of Italian mafias (both in Sicily and Calabria), argues, however, that their decline is primarily the result of law enforcement repression since the early 1990s. Yet, public prosecutors in the court of justice in Palermo still have a hard time doing their work. Facing both politicians and mafiosi in the dock, continually surrounded by bodyguards, behind the door of their office and outside when going and leaving the courthouse, they suffer death threats of mafia bosses sentenced to life in prison and receive little cooperation from the government. "I am not sure of my life," reported public prosecutor, Nino di Matteo, in a recent interview. Di Matteo grew up in Palermo with the stereotype that all Sicilians are mafiosi but shares the dream that honest Sicilians can liberate themselves from the mafia. "In spite of the problems I feel that I can contribute something" (Sandra Venema, *De Volkskran*t 8 May 2014, 10–11).

As indicated above, mafiosi draw substantially on Sicilian popular culture, on cultural codes "that were part of the local lexicon of many people …." Moreover, poverty and unemployment among the working classes, both a consequence of mafia, still provides recruiting fields for prospective aspirant mafiosi in both urban and rural settings. Together with culture and class, collusion seems to continually encourage mafia reproduction in western Sicily.

Coda

Today, the term 'mafia' is widely used as a synonym for organized crime. A still larger conflation of the term includes metaphorical and ironic references to any coterie wielding illicit power in formal organizations or institutions.

Abstract

The article gives an overview of academic writing on mafias. It provides a definition for this often sensationalized phenomenon which focuses on the governance functions mafias perform and their similarities to states. It contrasts mafias with other forms of organized crime. The article goes on to discuss how and why mafias emerge and exist in certain places in the world at certain times, what mafias do, how they organize, how they expand, and how finally they decline.

The word 'mafia' invokes vivid imagery: secret societies, bizarre initiation rituals, violent deaths, Tony Soprano, a severed horse's head at the end of a bed. Much of this imagery comes from the slew of films and television shows about mafias, which seem to have unending popularity. Of course, the cultural representation of mafias is often a long way from reality. The academic study of organized crime rather attempts to give sober analyses of the activities, structure and social organization of groups or networks of criminals, the functions they perform, and the harm they cause. This has become a burgeoning sphere in criminology though it is a notoriously difficult subject to conduct research on. While ethnographic accounts of organized crime are rare due to the nature of the subject, research can often employ qualitative methods combined with the study of police data and court cases. Wiretap data, for example, can be used to conduct quantitative and network analyses. Some academics also focus on the way 'organized crime' as a concept is constructed socially, politically, and culturally, and how it may be used and abused. In all this, it is necessary to clearly distinguish mafias as a distinct analytical object of study. In order to do this, we will first turn to definitions of what a mafia is. Then, giving examples from around the world, we will look at why mafias emerge in certain places at certain times, their activities, their organization and expansion, and, finally, their decline.

What Are Mafias?

An organized criminal group, according to the United Nations Convention against transnational organized crime (2004: p. 5), is "a structured group of three or more persons, existing for a period of time and acting in concert with the aim of committing one or more serious crimes or offences…in order to obtain directly or indirectly, a financial or material benefit." Other organizations and governments have a very similar understanding of organized criminal groups to this. In most definitions in the last decade, we can see the same familiar elements: a group must be enduring, commit certain serious crimes, and seek enrichment. Yet, over the decades there was not always such a consensus. Definitions by both academics and governments have changed. In 1963, after mafia turncoat Joseph Valachi had vividly testified to the McClellan Commission as to the existence of a structured, pervasive Italian–American network of criminals, 'organized crime' became virtually synonymous with 'Cosa Nostra' (meaning 'Our Thing,' the Sicilian, and Italian–American mob) in definitions. As research developed away from the fixation on Italian–Americans, other concepts such as 'hierarchy,' 'monopoly,' 'harm,' and 'network' all came in and out of fashion in defining organized crime (Varese, 2010).

Clearly, when we think of mafias, the United Nations definition would appear to fit very well. Yet, perhaps this is because that definition is in many regards a catch-all one and, therefore, unhelpful for analytically distinguishing between certain types of groups. Is there a difference, for example, between mafias such as the Triads (originally from Hong Kong), the Yakuza (Japan), Camorra (Naples, Italy), *vory-v-zakone* ('thieves-in-law,' or the Russian Mafia), or Cosa Nostra (Sicily and the US) and street gangs such as the Cribs and the Bloods or motorcycle gangs such as the Hell's Angels for that matter? How should we distinguish between the 'Ndrangheta, a mafia based in Calabria, Italy which controls and extracts tribute from businesses in the region through violence, and the rather less ruthless cheese smuggling network that operated across the US–Canada border selling cheap US cheese to hard-up Canadian restaurateurs on the black market?

On the UN definition both are organized crime, yet this seems to miss important differences. Moreover, the use and abuse of the word mafia does not help here either; the press dubbed the cheese smugglers the 'Poutine Mafia' after the famously cheesy and greasy Canadian dish. Just as many different phenomena can fit into the UN definition of organized crime, so 'mafias' are now everywhere and therefore nowhere. Arkady Vaksberg argued that there was a 'Soviet Mafia,' by which he meant the entire political system of the Soviet Union (Vaksberg, 1991). If mafias can be anything from cheese smugglers to governments of continent-sized countries what meaning can the term possess? Some therefore argue that the term 'mafia' should simply be discarded by criminologists, as it has at best no analytical purchase and at worst it is a dangerous slur used to tarnish undesirable groups, particularly immigrants. When attached to ethnic, national, or regional markers such as 'Italian,' 'Albanian,' 'Chechen,' 'Corsican,' or 'Turkish' to give some of the most obvious examples, the term 'mafia' stigmatizes.

Is there a sense in which the term 'mafia' can be rescued from this muddle? There are a number of scholars who argue that while mafias are certainly organized crime groups, they are a specific subspecies possessing clear features that distinguish them. Some emphasize the use of a hierarchical structure with clear bosses, others focus on the systematic use of corruption

and clientelist links with state agents as a distinguishing feature. However, perhaps the most powerful approach to understanding mafias is to focus on what they do. Diego Gambetta, in a groundbreaking work on the Sicilian Mafia, argued for seeing mafias as alternative governance providers, attempting, as states do, to monopolize the sale of protection over a given territory (Gambetta, 1993). Gambetta stressed that mafias are, furthermore, autonomous suppliers of this protection; they are not internalized within another entity, a business say, but sell protection and extract tax in return from individuals, organizations, and enterprises.

Borrowing from Gambetta and the Nobel Prize winning economist Thomas Schelling (1984), we can make the following distinction: organized crime groups attempt to monopolize the provision of some illicit service or product utilizing violence, whereas mafias are autonomous entities that attempt to monopolize the provision of protection over a given territory utilizing violence. In reality this may be quite blurred. Mafias may engage in other organized criminal activities, drug trafficking say, but as long they maintain this protection function at their core, they may be called a mafia. Clearly, the protection the mafia sells might simply be from itself, and we call this straightforward extortion. However, the evidence suggests that mafias in most cases generalize the sale of protection and are ready to actually provide the protection service should the need arise. A key insight from this distinction of mafias from other types of organized crime groups is that mafias provide governance in an unstable underworld that is naturally lacking in trust. Organized crime groups cannot turn to the police or the courts to resolve disputes and enforce agreements, and so often turn to mafias which induce the trust that criminal groups need to coordinate and operate.

This element of governance as central to understanding mafias has a clear debt to Max Weber and his definition of the state which he defined as the monopoly of legitimate force over a given territory (Weber, 1992). Indeed, this suggests that in essence mafias do just what states do; the distinction from the state is simply one of scale and legitimacy (Tilly, 1985). A number of criminological studies, inspired by Gambetta's work, have investigated groups in China, Russia, and Japan (Chu, 1999; Varese, 2001; Hill, 2006) and found that there were indeed mafias, in the strict sense that Gambetta uses the term, operating in these countries. The Yakuza, Russian Mafiya, Triads, Cosa Nostra, 'Ndrangheta, and so on, all have the protection function in common. This definition allows us to discuss and analyze certain other types of phenomena not usually associated with mafia activity. In Northern Ireland, for example, paramilitary groups which had primarily political goals also engaged in racketeering and extracted tribute over a given territory. In this sense, these groups are akin to mafias, distinguished only by their overtly political aims – something most mafias do not share. The focus then on monopoly and protection, in essence governance functions, allows us to analyze and define what groups we can legitimately call mafias.

Why Do Mafias Emerge?

The term 'mafia' first emerged into popular usage in nineteenth-century Sicily, a variation on an Arabic word that described masculine bravado and the refusal of authority. A theatrical play called 'I Mafiusi della Vicaria' about a Sicilian prison group that had its own rituals and rules toured Italy in the 1860s and popularized the words 'mafia' and 'mafioso.' But how and why did the mafia itself emerge in Sicily at this time? And why did some areas of the island prove more fertile breeding grounds for this phenomenon than others? Are the conditions that gave rise to the Sicilian Mafia the same in other countries that have seen mafias emerge?

Sicily is an island that has experienced centuries of colonization by foreign powers. By the middle of the nineteenth century, there was fierce resistance to the attempts of the Italian state to integrate the south into a newly unified nation. Trust in society was low. The end of feudalism had created a class of free peasants who could cultivate the land and profit from it, paying rents to landholders. A nascent market economy was emerging. Absent landlords needed protection of their estates and extraction of the highest rents possible, agricultural produce from the estates needed safe passage for goods from the inland to the coast. The central Italian state was weak in the region and could not provide this protection efficiently. It was in the context of low trust, weak state protection, increasing economic transactions, and class tensions that individual mafiosi, or enforcers, emerged. They autonomously resolved disputes, enabled the extortion of peasants, and provided for the safe passage of goods from the inland to the coast.

Mafiosi at this time protected the interests of anyone who would pay. Former guards of the estates who had lost their jobs during this period of economic change created a supply of violent individuals who sought out a role for themselves in the new economy and sold their services as entrepreneurs of violence. It is not clear that at this time secretive organizations – the mafia – had yet emerged but individual mafiosi had carved out a niche for themselves with a distinct way of behaving (Blok, 1974). In economic terms, these mafiosi met a demand for trust as, for a fee, they helped to reduce transaction costs by inducing trust in informal agreements, preventing defection in lieu of legal guarantees and contracts. Indeed, where the demand for such services is higher, in principle the greater should be the mafia presence. In Sicily, the west of the island produced many more mafiosi than the east, and this can be explained by the greater instances of absentee landlordism and the breakup of the land into smaller parcels at the end of feudalism creating a higher volume of economic transactions than in the east and greater unprotected movement of goods from the inland to the coast. The specificities of land reform then meant that demand for protection varied within the island. This simple fact undermines the common assumption that there is something specific to Sicilian mentality or culture that was crucial to mafia emergence.

The case of Sicily suggests that there are a number of conditions that appear necessary for the emergence of a mafia in a specific place and time. First, low trust among individuals and in the protection of the state to enforce contracts, resolve disputes, and protect individuals and entities is a usual condition of mafia emergence. Second, where a monopoly over property is broken up and there is a resulting increase in the number of transactions between newly emerging economic actors, the demand for trust increases. If the state is not able to meet this demand then alternative protection providers may

emerge. Yet this emergence is not a given. There must also be a supply of individuals who are able to meet the demand for protection, i.e., those trained in violence, as this is the key asset a mafia possesses. These conditions were present in the mid-nineteenth century in Sicily. They produced mafiosi and, finally, mafias there, which have continued in various forms up to the present day (Gambetta, 1993).

Postcommunist countries allowed a natural experiment to test this theory of mafia emergence. By the 1980s, many socialist countries were implementing moves away from the sluggish command economy, including the Soviet Union itself under Mikhail Gorbachev. With the end of the state's monopoly over production, which was complete by 1991, vivid stories began to emerge of violence-wielding groups fighting out mafia wars in newly independent Russia, reaching its bloody zenith in 1992 and 1993. After 70 years of totalitarianism, trust in the state and within society was low, Russia was virtually bankrupt, and justice institutions corrupted. Despite property rights being largely unprotected by the state, there was huge competition to take up the plethora of business opportunities in the new economy and to grab a slice of the privatization of state assets. In this context of low trust, increasing economic transactions, and virtual state collapse, mafia-like groups emerged in Russia and in most postcommunist countries.

The supply of entrepreneurs of violence came in many forms in different places depending on the reputational assets of the groups in question within their societal and cultural context. In Bulgaria, wrestlers, who were respected in society and had created wealth and connections due to travel to international competitions during the communist period, founded the strongest protection-providing groups. In Kyrgyzstan, former police officers predominated. In Russia, a range of actors, from veterans of the Soviet War in Afghanistan, to martial arts experts, and prison gang bosses known as 'thieves-in-law' or *vory-v-zakone* who had held pride of place in Soviet counterculture, competed and colluded to monopolize the provision of private protection. They were joined by the thousands of ex-secret service officers who had been released from service in order to shrink the police state in the 1990s. Due to their former links with the state, these officers were able to obtain licenses and form legitimate private protection agencies slowly forcing out erratic and violent competitors such as Chechen and Slavic gangs (Volkov, 2002).

Japan provides another example. While the Yakuza claim an ancient lineage going back to the seventeenth century, their primary activities were speculation and selling illicit goods on the black market as well as engaging in organized gambling. The Yakuza, then, for most of its history was engaged in organized crime but not mafia activities, as we have defined these. The end of feudalism in the 1860s did not change these essential functions of the Yakuza as the state maintained control over the process of economic change and absorbed potential violent entrepreneurs such as the samurai warrior class (abolished in 1873) into new military structures. Instead, the Yakuza only legitimately became a mafia in the post-1945 period when they began to provide protection services. Once again, a key feature of this time period was the decline of state power and huge upheaval in society with Japan's defeat in World War II. Under US control, Japan's police and security structures were virtually dismantled, Japanese police had no jurisdiction over Chinese and Korean former prisoners of war, and there was an influx of battle-hardened Japanese exsoldiers, as well as a growing black market demand for drugs (Hill, 2006). This is the point at which conditions were primed for the Yakuza, with its culturally specific history and imagery, to gain new resonance in society and take on the form of a mafia – to attempt to monopolize protection over given territories.

What Do Mafias Do?

As we have seen, mafias on the definition provided here, in essence, extort and sell protection to businesses and resolve disputes among both criminal and legitimate actors. In the underworld of crime where contracts mean nothing and the state cannot be used to enforce agreements, mafias find a natural role. Where they find it beneficial and not destabilizing, mafia members might also engage in illegal activities such as illegal arms or drug trafficking. They will also naturally look for ways to launder money, setting up companies and bank accounts fronted by straw men often in other jurisdictions. Certain criminal markets, heroin, for example, are seen as potentially highly violent and volatile, and mafias may be loath to engage in them. Other markets, such as human smuggling, may be difficult to enter as the nature of the activity does not benefit rather static, hierarchically structured, and relatively visible mafias and instead favors flat, highly fluid, and transitory, opportunistic networks (Zhang and Chin, 2003). Moreover, due to how sensitive mafias are to reputational damage, highly morally dubious activities such as human trafficking, running prostitution rings, or kidnapping are often discouraged or at least mafia members might engage in them individually without using the group name.

Thus, the volatile underworld and complex illegal markets might not always be the best source of revenue for the mafia. As well as governing the underworld of organized crime then, mafias find various roles in the legitimate economy. Legitimate companies, often stable and working from fixed locations, provide clear opportunities for mafias to extract tribute as well as potentially supply front and no-show jobs for individual mafiosi that bring in regular sources of income to show the taxman. The mafia can force itself into industries and maintain a presence there through the corruption of local politicians and police departments. Mafias can also be invited to provide its services in a specific market or industry where this is beneficial. Examples can be small scale, such as the Triad-enforced cartelization of bus routes in Hong Kong or of wholesalers in fruit and vegetable marketplaces in southern Italy and post-Soviet Georgia. In these cases, the mafia service is highly beneficial for market players, as the markets in question have very low start-up costs, demand remains high regardless of price, there is little product differentiation, and a large number of small firms compete (Gambetta and Reuter, 1996). The mafia prevent entry of competitors, facilitate cartelization, and organize the market. The cost of the mafia service should ideally be outweighed by the benefits of the reduction in competition.

Mafia involvement can extend to large legitimate industries and have pervasive effects. There are instances of mafias engaging in rigging tenders by enforcing a cartel agreement

among conspirators who agree not to undercut each other and to take turns in winning given tenders. Some large-scale industries become suffused with mafia activity. In the waste hauling industry in New York, for example, the mafia invested themselves in haulage companies and infiltrated professional associations. They imposed a cartel through controlling and enforcing the division of customers among haulage companies. In this way, Cosa Nostra were able to effectively divide up routes and customers, enforcing a cartel in places such as Long Island and New Jersey. Business owners were charged top rates for the unavoidable waste haulage service and, unable to find a different company willing to make a better offer, paid up, passing on the extra costs to customers.

Construction is another industry highly susceptible to mafia influence (Jacobs et al., 2001). The mechanism for control of construction in cities such as New York City and Montreal involves control over labor unions. The mafia was able to effectively threaten construction companies with delays and disruption to schedules by being able to instigate strikes. As many different types of workers are required to complete a building project – concrete pourers, scaffolders, teamsters, electricians, and so on – any disruption to any of these groups could cause delays and incur huge costs. Moreover, construction sites made for unmonitored spaces to conduct illicit business and for mafiosi to take up no-show jobs.

How Do Mafias Organize?

Mafia 'families' are usually not families at all, but hierarchies consisting of a limited number of mafiosi drawn from networks of socially close people. Classically, the hierarchy involves a boss, a small number of authoritative members close to him who control the equivalent of a team leader who, in turn, runs small groups of heavies doing the dirty work on the ground. Ritual initiation draws a boundary that establishes the rights and obligations of these different classes of members, with uninitiated members having fewer privileges and often being required to make heavy material and temporal investments. Such distribution of rights and obligations, and the expectations regarding the behavior of members are often written down or passed on verbally as a 'code of honor.' Such hierarchical structuring, the use of ritualized initiation, and codes of behavior are a rather uniform aspect of mafias from Italy to Russia, Japan, China, and in mafia-like groups such as the Hell's Angels, Mexican drug cartels, or US prison gangs.

It is no accident that hierarchy is a key component of mafias. Deferring to a boss allows conflict among members to be resolved efficiently, judgments brought and punishment meted out through established mechanisms. This creates stability, a benefit that outweighs the potential costs of a boss abusing his or her power. In case a boss misbehaves, or indeed any member, codes of honor serve a function analogous to a constitution or criminal code, defining the limits of the power of individual members, and stipulating behavioral norms and accompanying punishments for infringements. Such codes are highly detailed in the case of prison gangs such as the Mexican Mafia and La Nuestra Familia in California (Skarbek, 2011). These groups act as mafias in providing protection in prison as well as extorting and controlling drug-dealing gangs on the street. Their codes are presumably deliberately elaborate due to the highly uncertain environment of the prison and the potential for the abuse of power by members and bosses.

Ritual initiation is also a crucial element of mafias and results from the high barriers to entry mafias place on potential recruits. Recruitment is vital to the strength and resilience of a mafia, in that members need very specific skill sets and personal qualities, there is always a threat of undercover police infiltration, and recruiting poor members can affect the collective reputation of the group. As will be discussed below, reputation is utterly vital for survival. Most mafias require a significant self-imposed cost to be borne by a candidate upon entry, establishing credible commitment and binding them into the fortunes of the group. Committing murder, for example, is a cost that an undercover officer or undedicated candidate could not bear. The Numbers Gang, a South African prison gang, requires candidates to attack and wound a prison warden as part of initiation. Russian *vory* or thieves-in-law require that candidates have spent significant amounts of time in prison and have never worked or had any dealings with the state. Initiation can itself be physically excruciating. Yakuza candidates must mutilate themselves by removing their little fingers upon initiation. The Triads, on the other hand, while having relatively low barriers to entry, impose a high exit cost: death. Once joined, leaving is not an option. Again, in the Triads this potential future cost is constituted by taking oaths during elaborate ritualized ceremonies. The important functions played by these often bizarre practices perhaps explain why they are so prevalent among such a variety of groups from different parts of the world.

How Do Mafias Expand?

In the 1960s, the American criminologist Donald Cressey argued that Cosa Nostra was an expansionist rational bureaucracy slowly creeping through the American nation (Cressey, 1969). There has since been much questioning of Cressey's position. Economic arguments on the expansion of organized crime reasoned that organized criminal enterprises were much more likely to be small and localized given the conditions of risk they operated in (Reuter, 1985). These hierarchical mafia groups struggle to expand outside their locale, as their position is very much maintained by their reputation, and, being unable to advertise their services widely as a legitimate firm might, this will not travel too far. Furthermore, moving to new territory increases costs on monitoring members of the group operating at a distance and can create the grounds for deadly conflict with already established groups in new territories. Violence and conflict are undesirable, as they draw unwanted attention from law enforcement.

Despite this, there is evidence that certain groups have achieved high levels of coordination across large distances and territories as well as successful transplantation out of original locales. Wiretaps of Sicilian mafiosi in a bar in Montreal in the 1970s as well as other sources point to the existence of a mafia commission in Sicily, an organizing body over and above individual mafia families that enables coordination and regulation of activities and resolution of disputes over a large territory. Similarly, the Russian and post-Soviet mafias are

marked by high levels of mobility and appear to coordinate and communicate through the use of practices learned in the Gulag, the widely dispersed archipelago of labor camps in the Soviet Union. The ability to coordinate in that repressive environment has been transferred to post-Soviet organized crime enabling collection of regional collective funds (known as *obshchaki*) and collective decision making at so-called thieves' courts (known as *skhodki*).

However, the economic approach to mafia organization suggests that such high levels of coordination are rare. This approach places a great emphasis on the initial start-up costs of running a mafia firm in a given locale. There are initially large costs and high risks in producing violence in order to establish a level of credibility in the threats produced by potential mafia groups. Once these start-up costs have been taken on, however, mafias can reap economies of scale. Once credible commitment to use violence has been signaled, clients will pay for protection, dispute resolution, and other services without testing the enforcement mechanisms present behind these services (Reuter, 1985). In essence, at this stage just the word of the mafioso can be converted into economic value. Reputation, therefore, substitutes perfectly for the mafia's main production unit, violence, at no extra production cost. This is most likely why mafia usually have the most obvious and well-known 'brand names' ('Cosa Nostra,' 'Yakuza,' and so on), protected by violence, of any type of organized crime group. The brand does all the work in the mafia business. Expansion on the back of this reputation, therefore, makes economic sense and clients will seek it out: once one business has protection, the probability of victimization is heightened for unprotected businesses as crime is displaced. Thus, monopoly is the most likely outcome, as clients will rationally transfer their business to whoever possesses the strongest reputation based on the most credible threat of violence. Eventually, however, a geographical limit will be reached, past which the reputation does not travel, or where another mafia group has a stronger reputation for credible threats. The costs of using violence must then be taken on once again and mafiosi have to decide whether the costs of conflict and potential attention from law enforcement will be outweighed by the benefits of expansion.

Expansion does occur though, and sometimes between countries and continents. Mafias can expand into new territories through push factors, where repressive government policies in one country or region displace mafia activity into another, or through pull factors, where mafias make strategic decisions to move based on the perceived benefits of a receiving country. These factors include lax law enforcement and material opportunities. Federico Varese shows that push factors are more likely to be the reason for mafia transplantation but that mafias do not move that easily or that willingly (Varese, 2011). For example, in the mid-twentieth century, the Italian state believed it could help develop the south and reduce mafia influence by resettling mafiosi in northern regions, this had the unintended consequence of simply displacing mafia activity to northern Italy. The post-Soviet republic of Georgia enacted an extremely harsh antimafia campaign in 2005. This has partially caused a mafia war between Georgian expat groups in Moscow and expansion into Europe as witnessed by continent-wide raids in 2010 and 2013, which netted over 100 organized criminals from the post-Soviet space, the majority Georgians, as they flooded out of the country in the wake of government policy (Slade, 2012).

Once pushed out of a territory, other factors such as the structure of the local economy in the receiving country, the presence of a general migratory outflow from one country to another, and the levels of trust and demand for protection in the receiving locale, all effect the success of mafia transplantation. For example, the large exodus of Sicilians to the US at the end of the nineteenth century included some individuals who were members of mafias back in Sicily. Once in the US and in particular in New York City certain factors were conducive to the establishment of an overseas filial of the Sicilian mafia. The rise of prohibition and well-intentioned but misfiring police reform in New York in the 1910s resulted in a large unprotected market opening up. This facilitated the rise of Cosa Nostra and the establishment of mafia dynasties that are still with us today in New York, otherwise known as the Five Families (Varese, 2011).

Why and When Do Mafias Go into Decline?

Few criminologists are prepared to declare any mafia dead. It would be difficult to know for one thing whether a mafia, as a secretive organization, truly has died or it is simply dissimulating disappearance. Moreover, there are plenty of people for whom the mafia is a useful construct (Gambetta, 2009). Police departments can get extra funding and government support by playing up to the threat of a conspiratorial, hydra-headed mafia monster (Smith, 1976). Governments can blame shadowy mafia figures or immigrant alien conspiracies for problems of crime and violence and other failings, while 'transnational organized crime' can be invoked to demonize and justify meddling in other countries, particularly in the age of the 'war on terror' (Woodiwiss and Hobbs, 2009). There is no doubt that 'organized crime' and 'mafia' are terms that are used and abused for political purposes; figures concerning the economic power of organized crime groups and mafias can be but mere shots in the dark. Nevertheless, whatever the motive, states do occasionally attack the mafia. There are numerous examples of antimafia policies from different countries, all with varying levels of success. What factors might weaken the strength of mafias?

Many studies focus on state-centric factors to explain decline. Governments must make strategic decisions about when to attack the mafia, as it may prove to be an expensive activity which reaps little gains in crime control or at the ballot box. In some countries, governments face violent backlashes if the mafia is challenged. In Brazil, for example, the First Command of the Capital (the PCC, a prison gang) is able to virtually shut down the city of Sao Paolo if it chooses to oppose the state. Thus, mafias and states often simply exist in wary equilibrium of each other, often maintaining a negotiated connection through corrupt links on local levels. Still, at certain moments states can launch full-out attacks on mafias, though success is rarely a given.

In the US, the Racketeer Influenced and Corrupt Organizations Act of 1970 was a relatively successful attempt to curb organized crime. It allowed greater punitive measures against those who order commission of crime and engage in patterned acts of racketeering. On top of this, demographic change, reform

of the policing of cities granting increased federal oversight, and improved legislation have reduced corruption and the infiltration of traditional mafias on a local level in the US (Reuter, 1995). Administrative measures that aim at increasing transparency, such as the creation of trusteeships in organized crime-infiltrated industries, are credited with decreasing the influence of the mob in cities such as New York and Amsterdam.

In Italy, direct antimafia strategies, including legislation and law enforcement reform as well as civil society mobilization, implemented after the mob killings of the judges Falcone and Borsellino in 1992 have been relatively effective, at least in Sicily (Paoli, 2007). These measures include new law enforcement techniques and heightened police coordination including longer investigation times, the greater use of wiretapping, entrapment, state's witnesses, and the criminalization of activities that aid the mafia.

However, a simple emphasis on the policies of the state and the changes in the socioeconomic environment does not account for the vulnerabilities or resilient qualities that decide whether a mafia survives or succumbs to state attack. Strength in recruitment, for example, is a key variable in survival. Similarly, internal and external structuring of relations is vital for robust organization, effective adaptation, flows of information, and efficient monitoring and sanctioning. Yet, the organization of criminal activities is often risky, and constantly changing in conditions of permanent insecurity and uncertainty. Some scholars capture this by talking instead of *organizing* crime rather than the more presumptive *organized* crime (see, e.g., McIllwain, 2001; Morselli, 2008). This emphasizes the contingent-networked nature of organized crime and how these networks can possess vulnerabilities and weak points, or be poorly adapted to changing environments and disorganized in front of state power.

In explaining the decline of mafias, the primary emphasis then is on law enforcement, governance, political processes, and in some cases the structure and organizational change within mafias themselves. By combining an analysis of state policies, societal and economic change, and the adaptations of mafias in terms of recruitment, internal and external relations, depth and sources of resources available, and the shifting motivations of mafiosi, criminologists can create convincing accounts of why mafia groups can in some cases survive state attack, while in other cases be greatly weakened by it. Focusing on organizational vulnerabilities of organized criminals might help understanding of how best to tackle established and seemingly indestructible mafia groups, helping to explode the myth that the mafia is forever.

Abstract

This article makes an anthropological study of anthropological interpretations of magical beliefs and practices in non-Western societies. It contends that these interpretations must be situated and understood within the discipline's own culture whose fundamental guiding principle is the notion of 'human unity.' It further contends that, although the target of these interpretations is ethnocentrism, paradoxically, they turn out to be ethnocentric themselves.

The magical, broadly and somewhat loosely understood as belief in the existence and efficacy of supernatural forces, has been an area of intense anthropological interest from the inception of anthropology as an academic discipline in the late nineteenth century to the present day. This interest has little if anything to do with a penchant for the study of the occult and the exotic and much to do with the discipline's most fundamental underlying assumption and guiding principle – the idea of human unity. On the one hand, this idea refers to what E.B. Tylor posited in the nineteenth century as 'the psychic unity of mankind,' the ability to think rationally, which many of Tylor's contemporaries doubted in the case of what they perceived as 'primitive people.' On the other, and over and above Tylor's postulate, it refers to cultural equality, implicit in the twentieth-century notion of cultural relativism and assumed in all anthropological critiques of ethnocentrism, effectively Eurocentrism – the belief in the cultural superiority of Europe and the West.

To put it schematically, the question that anthropologists were called upon to answer or themselves felt the need to answer was the following: if native populations are rational people 'like us,' as the principle of human unity suggests, how is one to explain their involvement in apparently irrational beliefs and practices like magic? Anthropology's answer to this question is entangled in a paradox, which is only now beginning to come to light and be discussed. In explaining native involvement in magical beliefs and practices as something reasonable, anthropologists also explain native culture away. Unwittingly and unwillingly, they end up being ethnocentric themselves.

This article examines anthropological explanations of magic in the context of the various efforts to uphold the principle of human unity. It begins with social evolutionism and explores the views of E.B. Tylor, the paradigmatic figure of Victorian anthropology. It then moves on to the early twentieth century and the work of two key figures, Malinowski and Evans-Pritchard, both of whom moved away from the Victorian understanding of magic as a pseudoscience and began to treat it as a symbolic phenomenon. By the 1960s, symbolic interpretation becomes dominant and the article explores the work of two anthropologists who played a pivotal role in the consolidation of this paradigm – Mary Douglas and Clifford Geertz. It then moves on to two studies within the Marxist problematic, which link magic to local experiences of capitalism: Michael Taussig's explanation of devil worship in South America and Jean and John Comaroffs' discussion of 'occult economies' in postapartheid South Africa. The article concludes with a brief reference to the recent recognition that symbolic interpretation explains native culture away and the suggestion from some quarters that the notion of culture ought to be replaced by the notion of ontology.

Social Evolutionism: Magic as a 'Pseudoscience'

The nineteenth century was the time when anthropology became a recognized academic discipline. It was also the time when the achievements of the natural sciences had captured public imagination and for many provided tangible proof of the superiority of Europe vis-à-vis the rest of the world. Anthropologists were not immune to this vision of the world. Nonetheless, some, most notably Tylor, were not prepared to accept the more extreme form of this vision, which treated the magical beliefs and practices of native populations as an indication of a radically different mentality – so different, in fact, as to cast doubt on their humanity. Tylor's problem, therefore, was to explain magic in a way that was consistent with his postulate of the psychic unity of mankind, in effect to demonstrate that, although 'primitive people' were apparently different from Europeans, in a fundamental sense they were also the same.

For Tylor (1874), there was no doubt that magic was "one of the most pernicious delusions that ever vexed mankind" and characteristic of "the lowest known stages of civilization." It was a 'pseudoscience,' a system of thought and practice that attempted to manipulate the empirical world but was unable to do so. Yet this did not mean that it was the product of inherently different minds. The human mind, he argued, operates everywhere and at all times with the same principles of thought – by associating ideas on the basis of analogy and cause and effect. 'Primitive' people, being at the lowest stage of intellectual development, a stage characterized by the kind of innocence one finds in children, were particularly prone to making errors and magic was a paradigmatic example. To use Tylor's own terminology, 'primitive' people mistake 'ideal for real connections,' that is, they treat events that are only accidentally related as if they cause one another. There is nothing in reality that connects the crowing rooster with the rising sun, but because the two events occur regularly and sequentially, 'primitive' people assume that the former causes the latter. Magic is

the practical application of such misconceptions. The rooster is made to crow so that the sun will rise. The moral of Tylor's story was that 'primitive' people, being like children, will eventually grow up and begin to think and act rationally.

Twentieth-Century Paradigms

For reasons that are yet to be fully explained, by the early twentieth century, the social evolutionism of Tylor and his contemporaries and the ethnocentrism that guided it had become less palatable. And so was their explanation of magic. The issue was no longer to demonstrate that 'primitive' people are *potentially* rational but that magic itself was, if not strictly speaking rational, certainly a reasonable way of dealing predicaments that are often universal. The first anthropologist to treat magic along these lines was Bronislaw Malinowski.

Magic as a Source of Hope and Optimism

Malinowski spent the years of the First World War among the natives of the Trobriand Islands of the southwest Pacific and developed a different understanding of the place of magic in native life. In his extended essay *Magic, Science and Religion* (1954) he sets out to show that much of what had been written about magic was speculative and had little basis in reality. To this effect, he engages both Tylor and the French philosopher-turned-anthropologist Lévy-Bruhl. The former, Malinowski argues, depicts natives as if they were intellectuals seeking to find answers to theoretical questions, and the latter as being "hopelessly and completely immersed in a mystical frame of mind" (1954). In contrast to both, Malinowski found the natives of the Trobriand Islands to be practical people concerned with practical things: fishing, gardening, building canoes, and tribal festivities. This is not to say that they did not also practice magic. Yet they did so only under specific circumstances.

In a celebrated example, Malinowski shows that when fishing in the lagoon, the Trobrianders did not resort to magical rites; they relied instead on their knowledge and skill. In open-sea fishing, however, which is "full of danger and uncertainty, there is an extensive magical ritual to secure safety and good results" (1954). This and other similar examples, Malinowski argues, demonstrate that natives turn to magic only in situations of emotional stress, when they reach the limits of their knowledge and cannot control the outcome of their actions. Malinowski concluded, therefore, that far from being a cognitive mistake or a sign of mystical mentality, magic fulfills an important psychological function: it ritualizes optimism and enhances human confidence and hope.

Evans-Pritchard: Transition to Symbolism

Although highly suspicious of evolutionism, Malinowski was not able to go beyond the other tenet of Victorian anthropology – that the primary aim of magic was the attainment of practical results. Nor, by extension, was he able to go beyond the notion that magic was ultimately a pseudoscience. The shift from this utilitarian perception to one that views magic as a meaningful and meaning-generating phenomenon came with Evans-Pritchard (1976) in his classic study of Zande witchcraft. Evans-Pritchard was working within the broad sociological problematic developed by Emile Durkheim, which emphasized social stability and treated religion as a social institution that contributed to it. In his study of the Azande of Central Africa, Evans-Pritchard extended the argument to witchcraft. At the same time, he continued the debate with Lévy-Bruhl that Malinowski began. It is in this confrontation with the French philosopher that he lays the ground for the paradigm that was to dominate subsequent anthropological studies of magicoreligious systems.

Evans-Pritchard analyzes Zande witchcraft along two axes. The first explores how witchcraft contributes to the cohesion of Zande society – its social function. The other examines the condition under which the Zande have recourse to it – its cultural function. Witchcraft embraces a system of values that regulate Zande behavior. No one knows for certain who might be a witch, but spiteful, moody, ill-tempered, and bad-mannered individuals are prime suspects. Belief in witchcraft acts in a way that encourages more positive dispositions and helps to curb antisocial behavior. If the Zande suspect that their neighbor is a witch, they are careful not to offend him/her from fear of being bewitched. Similarly, spiteful and ill-tempered individuals do not wish to be accused of being witches from fear of revenge and are therefore likely to change their behavior. In this way, says Evans-Pritchard, friction and conflict are kept in check and the cohesion of Zande society is maintained.

Yet social stability is hardly what the Zande have in mind when they make witchcraft accusations. Their aim rather is to explain misfortune in a way that makes it socially relevant and meaningful. Their explanation no doubt refers to a supernatural cause – witchcraft – but this does not mean that the Zande are ignorant of the natural causes of events, much less that they have a mystical frame of mind as Levy-Bruhl had argued about 'how natives think.' To use a well-known example, sometimes old granaries collapse and injure people and this, like other accidents, is attributed to witchcraft. The Zande are well aware that wood decays and that termites eat away the foundations of granaries; they know that it is because of these natural causes that old granaries collapse. What they try to explain through witchcraft accusations is the timing of the event. Why should a particular granary collapse "at the particular moment when these particular people were sitting beneath it? Through the years it might have collapsed, so why should it fall when certain people sought its kindly shelter?" (1976) Witchcraft offers an explanation over and above natural causation, one that links the collapse of the granary with the fact that certain people were at that point in time sitting underneath it. We, Evans-Pritchard points out, do not have an explanation for the intersection of the two events; we say that they have independent causes and that their intersection is an accident. The Zande provide the missing link; they say it is witchcraft. By making the event socially relevant they are not so hopeless. They can act on it.

Magic as a Symbolic Phenomenon

After Evans-Pritchard's ground-breaking book, the notion that magic is a symbolic phenomenon, something that reflects underlying social and cultural realities rather than an irrational

practice becomes the central argument in most anthropological studies. In what follows, the author discusses several well-known works, beginning with Douglas's (1966) famous analysis of pollution and taboo (*see* Taboo).

In this book, Douglas deals with the accusation that 'primitive' people do not make a distinction between the holy and the unclean – an accusation whose implication is that 'primitive' societies have a magical orientation toward the physical world; that people in these societies believe nature to be inhabited by unpredictable and often malevolent supernatural forces; and that contact with unclean things, such as menstrual blood or corpses, brings one perilously close to these forces.

Douglas's response to this accusation is that notions of pollution and taboo are symbolic expressions of conceptual and social disorder, the idiom through which people come to terms with unclassifiable things and intractable social contradictions. Dirt, Douglas points out, is matter out of place, the inevitable outcome of every attempt to classify things and establish a conceptual grip on the world. It is the result of a universal human predicament, the need to transform chaos into a cosmos, that is, a meaningful world. Those things that do not fit our conceptual schemes and hence contradict and undermine them are everywhere designated as dirt; they become dangerous and are either suppressed or avoided. The threat is real enough, since unclassifiable things undermine our ability to construct and lead meaningful lives. At the level of culture, this danger is expressed through beliefs in pollution and defilement and concomitant rules of avoidance.

Contradictions in conceptual schemes are often reproduced in contradictions at the social level. Take, for example, the notion of sexual pollution and the related idea that it is dangerous for men to come into contact with menstrual blood. This notion, Douglas points out, is widespread among New Guinea tribes, but it is particularly pronounced among the Mae Enga. In this tribe, men believe that sexual intercourse weakens male strength so that even within marriage it is reduced to the minimum necessary for procreation. This belief may appear as an irrational fear, but as Douglas explains, the taboo reflects conflicts embedded in Enga society. The latter consists of exogamous clans that compete fiercely for prestige and power and are hostile to another. The exogamous clan system, however, forces men to marry outside their own clan, that is, women who come from the enemy's camp. In their pollution beliefs and practices of sexual avoidance, the Enga are trying to overcome symbolically a fundamental social contradiction – building marriage and family on enmity.

Less than a decade after Douglas's book, Geertz (1973) wrote a seminal essay that was to consolidate the symbolic approach in the study of magicoreligious systems. Geertz's essay is entitled Religion as a Cultural System but the reference to 'religion' should be understood to mean any metaphysical system, including magic. Geertz's essay is inspired by, and draws on, Evans-Pritchard's discussion of Zande witchcraft. It also draws on Max Weber's religious sociology, but unlike the latter who was working within an evolutionary paradigm and treated magic as historically prior to religion, Geertz does not make a distinction between the two. Geertz's argument is that 'religion' is a cultural system that helps people to maintain faith in the ultimate meaningfulness of life. It does so by accounting for all those anomalies in human experience – paradoxes, puzzles, ambiguities – that threaten to undermine the general order of existence. There are three points, according to Geertz, where chaos, "a *tumult* of events which lack not just interpretations but *interpretability*" threatens to enter into the world: at the limits of people's ability to explain, endure suffering, and make sound moral judgments. Coming up against these limits time and again, Geertz (1973) points out, "sets ordinary human experience in a permanent context of metaphysical concern and raises the dim, back-of-the-mind suspicions that one may be adrift in an absurd world." It is at such difficult moments that religion intervenes and affirms the ultimate meaningfulness of the world. It does so not by denying that there is ignorance, suffering, and injustice in the world, but rather by denying that such things are intrinsic to reality, an inescapable fact of the world.

The last two works to be examined are Taussig's (1980) book *The Devil and Commodity Fetishism in South America* and a recent article by Comaroff and Comaroff (1999) entitled Occult Economies and the Violence of Abstraction: Notes from the South African Postcolony. Both are influential works. Although situated within the Marxist problematic, which has been historically unreceptive to the significance of magicoreligious systems, they decisively adopt a symbolic approach. They interpret native beliefs in the magical and the occult as a means of making sense of capitalism and dealing with its impact on everyday life.

In rural Colombia, native people working on sugarcane plantations often enter into a secret contract with the devil. In return for their soul, the devil helps them work faster and increase their production and hence their wages. Such contracts, however, are said to have several negative consequences. To begin with, it is said that there is no point in investing the extra money in capital goods, such as livestock or land. The money earned with the help of the devil is believed to be inherently barren: the animals will die and the land will become sterile. Moreover, those who enter into such contracts are said to die young and in pain. In short, even though people improve their conditions in the short run, the long-term effects of dealing with the devil are destructive. How are these beliefs and practices to be interpreted?

The devil, Taussig argues, signifies the way in which local people are trying to come to terms with the capitalist relations of production. It also expresses their evaluation of, and resistance to, the new way of life. Having been uprooted from their ancestral homes, the local peasants are now forced into wage labor. Their traditional way of life based on reciprocity and cooperation has been displaced by the capitalist mode of production, exploitation by the landowners, and competition among themselves. It may be the case that they are now financially better off than before, but as the devil stories suggest, the quality of their lives has drastically deteriorated. The devil is an apt symbol for expressing the new order of things.

The Comaroffs, (1999) article is concerned with the deployment of magical means for the attainment of material ends – the 'occult economies' of the title – in postapartheid South Africa. These include a wide range of phenomena: from ritual murder of people suspected of witchcraft to the sale of body parts to be used in potions for success in one's pursuits

and the production of zombies who work for free and enrich in this way their 'employers.' Although such practices are not new, there has been a dramatic increase in the postrevolutionary period and the aim of the article is to explain 'why *now*?' The authors point to what they call 'millennial capitalism,' the promise of prosperity for all and the realization that even in the postapartheid period it is still only the very few that actually prosper. Magic is a culturally familiar idiom through which people attempt to make sense of this reality and the 'mysterious mechanisms of the market.' If the majority is left out of the promise of prosperity, many people reason, it must be because 'arcane forces are intervening in the production of value, diverting its flow for selfish purposes.' This, the authors argue, explains both the pursuit of new magical means for attaining wealth and the effort to eradicate those who are thought to monopolize it through such means.

Culture or Ontology?

The author has already suggested that contemporary interpretations of magic are entangled in a paradox: in trying to combat the ethnocentrism that portrays magic as an irrational practice, they end up, unwittingly and unwillingly no doubt, being ethnocentric themselves. It may be the case that magic ritualizes hope and optimism, that witchcraft makes accidents meaningful, that sex avoidance expresses social conflicts, that the devil symbolizes the nature of capitalism, and so on but this is not how the people involved in these beliefs and practices understand them. As far as they are concerned, magic before a fishing expedition in the open sea ensures safety and a good catch, witchcraft is a force in the body of the witch that flies at night and attacks its unsuspecting victims, contact with menstrual blood causes serious harm, and the devil is a malevolent supernatural force. If anthropological interpretations are valid, the inescapable conclusion is that natives suffer from a 'cultural unconscious' (Argyrou, 2002). They may not be irrational but they are certainly ignorant of the true meaning of their magical beliefs and practices.

It is problems such as these that seem to be behind a recent call to replace the notion of culture with that of ontology (e.g., Viveiros de Castro, 2003; Holbraad, 2010). The problem with cultural analysis, according to the argument, is that it posits one reality that is open to different representations – one nature, many cultures. This is a problem because in this schema only one representation can be valid – usually the Western representation. An ontological perspective, by contrast, posits multiple realities, which means that other ways of life can no longer be treated as misrepresentations of reality. They are realities in their own right and if anthropologists are to understand them, they need to expand their conceptual horizons.

Can this theorization of other ways of life save the day? Without further elaboration of the thesis, it is too early to tell. One question, however, may be raised: does this thesis not posit a reality (of multiple ontologies) that the natives are once again not aware of?

This article is a revision of the previous edition article by R. Schlösser, volume 15, pp. 10148–10155, © 2001, Elsevier Ltd.

Abstract

Neuroimaging techniques provide *in vivo* measures of brain structure and biology. They have revolutionized the study of psychiatric disorders by enabling neurobiology to be linked to the clinical expression and development of disorders, and the effects of treatment or behavioral challenges. This article provides an overview of the main techniques – Magnetic resonance imaging, including functional magnetic resonance and magnetic resonance spectroscopy; positron emission tomography; and single photon emission computed tomography – and illustrative key findings in psychiatry to highlight their application. It concludes by discussing future directions.

Introduction

Psychiatric disorders are challenging to study, not least because it has proven hard to produce preclinical models that reproduce key aspects of their phenotypes. A number of neuroimaging techniques, such as computerized tomography, have been available for decades and provide a means of studying the neurobiology underlying these disorders. However, the development of magnetic resonance (MR) and molecular imaging techniques and their application to study the brain has a number of advantages over earlier techniques, and has contributed to an impressive expansion in understanding of the neurobiological basis of psychiatric disorders. Magnetic resonance imaging (MRI) provides data on brain structure that can be used to identify regional or global alterations in a disorder. Functional magnetic resonance imaging (fMRI) enables investigation of neuronal activation, generally during a cognitive or behavioral task or a drug challenge. Neurochemistry can be investigated using magnetic resonance spectroscopy (MRS). Positron emission tomography (PET) and single photon emission computed tomography (SPECT) are molecular imaging techniques that also provide data on brain chemistry, as well as enabling the interrogation of other aspects of brain function, including receptor levels, blood flow, and metabolism.

Neuroimaging has revolutionized the study of psychiatric disorders in a number of ways. First, the *in vivo* measures can be related to clinical features to provide insights into the nature of the brain alterations underlying specific aspects of the disorder. Second, they can be applied at different stages of the disorder to elucidate the biology underlying stages of the disorder and response to treatment. Third, the measures can be repeated to illuminate the nature of changes over time with the development and progression of the disorder. Fourth, neuroimaging can be used to aid drug development, for example, by identifying targets and determining whether a drug enters the brain and acts in the right region. This article discusses the major uses of neuroimaging in psychiatry and illustrates them with key examples from particular disorders. It is not intended to be all encompassing and suggestions for further reading are provided at the end.

Structural MRI

Principles

MRI takes advantage of the physical properties of atomic nuclei, such as hydrogen, that are electrically charged. These behave as charged spinning tops that produce a magnetic field. In the MRI scanner an external magnetic field is imposed, which causes these nuclei to align either parallel or antiparallel to the field. External electromagnetic radio frequency (RF) pulses are then used to move the spinning nuclei out of their initial alignment, which is accompanied by a change in their energy state. When the RF pulse is removed, the nuclei relax back to their equilibrium state and this change in their energy state is accompanied by the production of an RF signal, which is detected by coils within the scanner. This signal is reconstructed to produce an MR image. Protons in different tissues return to their equilibrium states at different relaxation rates, depending on the local environment of the protons, which provides information on the nature of the tissue. The application of additional magnetic fields results in predictable changes in the RF signal that can be used to provide spatial information. The basic unit of the resulting three-dimensional image is a voxel (volumetric picture element). Voxel size depends on the resolution of the scanner. In general, MR scanners with higher magnetic field strength (measured in Tesla) have higher resolution. The intensity of the MR signal in a given voxel depends on the proton density of the tissue in the voxel. As hydrogen atoms have protons, tissue with high water (containing two hydrogen atoms) content provides a high intensity signal.

Functional Magnetic Resonance Imaging

General Aspects

MRI techniques have been developed to provide information on the function of the brain as well as its structure. This enables functional changes to be investigated in central nervous system disorders or during behavioral, cognitive, or emotional tasks. The most widely used techniques in psychiatry are described below.

Blood Oxygen-Level-Dependent (BOLD) fMRI

Probably the most widely used fMRI approach is based on the BOLD-contrast imaging technique to provide an indirect index of change in neuronal activity. This takes advantage of the fact that there is a difference in the magnetic properties of blood depending on whether it is oxygenated or not, as deoxyhemoglobin is paramagnetic and oxyhemoglobin is diamagnetic. Neuronal activation results in a local change in blood flow that is beyond the metabolic demand, leading to a local increase in oxyhemoglobin and a decrease in deoxyhemoglobin. This change is associated with an increase in the T2* signal, which can be detected in the scanner. BOLD fMRI studies generally involve the subject performing a cognitive or other task in the scanner. The change in signal during this task relative to a baseline is then taken as an index of brain activation during the task. It is important to note two things about BOLD fMRI studies. First, they are based on signal change – this means that the baseline (control) condition can be as important as the task. Second, the signal change is generally quite small – in the order of one to five percent.

Studies usually have either a block- or event-related design. In a block design, one condition is presented for a period of time followed by the other condition, and this sequence is generally repeated. A limitation of this approach is the fixed order. Whereas, event-related designs model the hemodynamic response to each condition. This avoids the need to present conditions in a fixed order and enables timings to be varied.

Perfusion fMRI

Brain blood perfusion can be studied using MR either by using a paramagnetic contrast agent (such as gadolinium) that is injected into a vein, or changing the magnetic properties of the arterial blood entering the brain to 'label' it. The latter technique, arterial spin labeling, has the advantage of being noninvasive. Both techniques provide physiologically quantifiable measure, in contrast to BOLD fMRI.

Diffusion-Tensor fMRI

Water molecules are in constant random motion in the brain. Diffusion-weighted fMRI takes advantage of the magnetic properties of water, which can be detected in the scanner to index the motion of water molecules. In some ordered tissues, the motion of the water is constrained in certain directions. For example, in a bundle of parallel axons water can more readily diffuse along the main axis of the bundle than across the bundle – diffusion is anisotropic. Diffusion tensor imaging (DTI) is frequently applied to measure the degree of anisotropy in white matter tracts to detect differences in the integrity of tracts between patients and controls, for example.

Magnetic Resonance Spectroscopy

Magnetic resonance spectroscopy (MRS) is used to investigate neurochemistry. It is based on the fact that nuclei of one type resonate at different frequencies depending on their local chemical environment that depends on the molecular structure of a given neurochemical. This phenomenon is termed the chemical shift. The chemical shift thus provides a signature that can be used to detect particular neurochemicals in the brain. The most widely used MRS techniques in the brain are ^{1}H-MRS and ^{31}P-MRS. ^{1}H-MRS is well established for the detection of N-acetyl aspartate (NAA), creatine–phosphocreatine (Cr–PCr), glutamine, glutamate, aspartate, and lactate, and increasingly for gamma-aminobutyric acid. NAA is an amino acid generally considered to be a neuronal marker.^{31}P-MRS is used to measure brain membrane phospholipids and high-energy phosphate metabolism.

Molecular Imaging with Radiolabeled Ligands

General Aspects

PET and SPECT are molecular imaging techniques that provide *in vivo* information on biological molecules. They use very small quantities of radiolabeled molecules, known as radiotracers. These emit photons that can be measured in the scanner. Thus the localization and behavior of the radiolabeled molecule can be determined *in vivo*. Any substance that can have a radionuclide attached has the potential to be developed into a PET or SPECT ligand. The usefulness of particular ligand depends on its properties and target. Commonly available ligands target specific receptors, enzyme function, inflammatory markers, brain blood flow, and metabolism. It is also possible to index change in transmitter levels following a drug or cognitive challenge.

Principles

To obtain PET and SPECT images, the volunteer receives a radiolabeled ligand intravenously. Thus both techniques involve exposure to a small amount of radiation. PET uses positron emitting radionuclides such as carbon-11 (^{11}C), oxygen-15 (^{15}O), and fluorine-18 (^{18}F). These have short half-lives – meaning that they decay rapidly, generally within minutes and up to about 110 min in the case of ^{18}F. As a consequence, they need to be used quickly, which usually means they generally have to be made on-site and necessitates expensive equipment and skilled radiochemistry to be available. On the other hand, the common SPECT radionuclides such as technetium-99 (^{99m}Tc) or iodine-123 (^{123}I) generally have much longer half-lives – from hours to days. This means that they can be made off-site and potentially used for a number of syntheses. Another key aspect of the difference in the radionuclides used in the two techniques is that those used in PET tend to be relatively easily incorporated in many biological molecules. In contrast, the radionuclides used in SPECT tend to be rarely found naturally in biological molecules, and therefore incorporating them to make a successful radiotracer can be more difficult. Generally, it is important to know whether the addition of the radionuclide to make the radiolabeled ligand alters the properties of the molecule being labeled, or its behavior *in vivo*. This is often more of an issue in developing SPECT ligands because the radionuclides are rarely found naturally in biological molecules.

Findings

This section reviews some of the main findings from neuroimaging studies in psychiatry. It focuses on schizophrenia, affective disorders, and Alzheimer's disease, as these have been among the most extensively studied psychiatric disorders and provides a number of examples of the use and potential of neuroimaging techniques in psychiatry. It is intended to illustrate how these techniques have been used to advance understanding of psychiatric disorders and their potential for clinical application.

Schizophrenia

Structural Studies

There have been over 100 structural MRI studies in schizophrenia to date (Ellison-Wright et al., 2008). These have unequivocally demonstrated that there are structural alterations seen on average in people with schizophrenia, although it is important to note that structural alterations may not be seen at the individual level (Ellison-Wright et al., 2008). Increased ventricular volume and reduced total gray matter are among the most consistent findings (Ellison-Wright et al., 2008). The ventricular enlargement is likely to reflect loss of volume in other structures rather than an abnormality in the ventricular system per se. Gray matter volume in frontal and temporal lobe regions is consistently reduced, and generally the reductions in these regions are larger than in other regions, suggesting some regional specificity (Ellison-Wright et al., 2008). These changes are also seen in first episode patients at onset of schizophrenia and before treatment, indicating that they are not solely attributable to the effects of antipsychotics or chronicity. Furthermore similar, although generally less marked, structural alterations are also seen in the prodrome to schizophrenia, and seem to progress with the onset of the disorder (Pantelis et al., 2003). Longitudinal studies from the onset of the disorder have also shown further gray matter loss and ventricular enlargement during the course of schizophrenia (Ho et al., 2011). There is considerable controversy over whether these changes reflect a pathophysiological process or are a consequence of other factors such as antipsychotic treatment (Ho et al., 2011). DTI measures indicate that there is reduced integrity of white matter tracts in schizophrenia as well, indicating that alterations are not limited to gray matter alone, and highlighting that schizophrenia involves loss of connectivity between regions.

Functional studies

There have been a large number of functional imaging studies in schizophrenia, beginning with PET and SPECT imaging studies in the 1980s. These have shown that schizophrenia is associated with reduced cerebral blood flow and glucose metabolism, particularly in frontal regions, and to link them to symptoms (Davidson and Heinrichs, 2003). Subsequent fMRI imaging has extended these findings to show altered BOLD responses during a large number of cognitive and emotional tasks. Executive function is one domain of cognitive function that is consistently impaired in patients with schizophrenia. A meta-analysis of over 40 fMRI studies of executive function tasks in schizophrenia has found a remarkably consistent pattern of altered BOLD responses, with reduced activation in frontal cortical regions (including the dorsolateral prefrontal cortex) and thalamus, and reduced activation in the anterior cingulate cortex (Minzenberg et al., 2009). It is thus clear that there is altered brain function in schizophrenia.

Neurochemical imaging studies have provided evidence on the nature of the molecular abnormalities that may underlie the functional brain alterations in schizophrenia, and symptoms. A meta-analysis of over 50 molecular imaging studies of the dopamine system has pin-pointed the nature of the dopaminergic changes in the disorder (Howes et al., 2012). It identified that while there is no marked alteration in D2/3 receptor availability, there is a marked and consistent elevation in the capacity for striatal dopamine synthesis and dopamine release in patients with schizophrenia. The same alterations have also been recently reported in the prodromal phase prior to the onset of psychosis (Howes et al., 2011b), and found to increase with the onset of psychosis (see **Figure 1** and Howes et al., 2011a). MRS imaging has identified alterations in glutamatergic indices in schizophrenia, although, in contrast to the consistent elevation in the presynaptic dopaminergic findings, there is inconsistency (Marsman et al., 2013). The lack of consistency may reflect the stage of illness or effect of antipsychotic treatment – with some evidence suggesting that there are elevations early in the illness that are reduced with treatment.

Affective Disorders

Structural and fMRI studies

Unipolar depression is associated with reduced brain volume, although alterations are in somewhat different regions to those seen in schizophrenia and are less marked. Meta-analysis indicates that reductions are seen in regions involved in emotional processing such as the orbitofrontal cortex, cingulate cortex, hippocampus, and striatum, while there is an increase in pituitary volume (Arnone et al., 2012a). There is also consistent evidence linking the presence of increased white matter hyperintensities – an indicator of possible focal infarcts or other damage – to depression. In addition to structural alterations, there is evidence for functional brain changes in depression. Converging data from fMRI studies increased activity in a number of brain regions involved in the processing of emotion, particularly to negative stimuli in the disorder (Kupfer et al., 2012). The amygdala, ventral striatum, and medial prefrontal cortical regions show increased activation to negative emotional stimuli (Arnone et al., 2012b). Interestingly these alterations have been found to be reversed by treatment with serotonergic antidepressants (Harmer et al., 2009; Kupfer et al., 2012). Furthermore response to serotonergic antidepressants is predicted by the activity in these regions.

Molecular imaging studies

Given the importance of serotonergic drugs in the treatment of depression, it is not surprising that molecular imaging studies have particularly focused on the serotonin system. Serotonin$_{1A}$ receptors are thought to play a key role in maintaining stable serotonin transmission and to be involved in the mechanism of antidepressant treatment. Most of molecular imaging studies of these receptors have found that patients with depression have reduced 5-HT$_{1A}$ receptor density, particularly in the raphe

Figure 1 Showing the change in striatal dopamine synthesis capacity with the onset of psychosis – illustrating the value of neuroimaging to investigate pathophysiological changes during the course of psychiatric disorders. Taken with permission from Howes, O., Bose, S., Turkheimer, F., Valli, I., Egerton, A., Stahl, D., Valmaggia, L., Allen, P., Murray, R., Mcguire, P., 2011a. Progressive increase in striatal dopamine synthesis capacity as patients develop psychosis: a PET study. Molecular Psychiatry 16, 885–886.

nucleus. However, increased 5-HT_{1A} receptor density has also been reported. This apparent discrepancy may be due to methodological differences, particularly whether the 5-HT_{1A} binding potential is determined using the 'gold standard' arterial input function, or using a reference region (Shrestha et al., 2012). Recently serotonin$_{1A}$ receptor levels have been found to closely correlate with regional gray matter volumes, particularly those involved in emotional processing, in patients with depression, suggesting that these abnormalities are linked (Kraus et al., 2012).

The 5-HT_{1B} receptor is another presynaptic autoreceptor, which inhibits serotonin and other monoamine neurotransmitter release. A 20% decrease in 5-HT_{1B} binding potential in the ventral striatum and pallidum of patients with depression has been reported, suggesting there may be abnormalities in other autoreceptors in depression as well (Murrough et al., 2011). The serotonin transporter has been another focus of investigation in depression, particularly because of the importance of serotonin transporter inhibitors in the treatment of depression. Although there have been some conflicting results, the majority of studies have found decreased serotonin transporter binding in patients with depression (see recent examples: Selvaraj et al., 2011; Reimold et al., 2011). PET studies have also found evidence for alterations affecting one of the enzymes that break down monoamines. Specifically the density of monoamine oxidase-A (MAO-A) has been found to be elevated in depression (Meyer et al., 2006), suggesting that the metabolism of monoamines is increased in depression. Based on this, Meyer et al. (2006) hypothesized that the increased density of MAO-A in depression is the primary driver of reduced monoaminergic signal transduction in depression. This suggests that dopaminergic and norepinephrinergic systems will be affected as well. There is some evidence of alterations in the dopaminergic system in depression, although changes have not been marked with slight decreases or no change in D_1 and D_2 receptor density, and a decrease in dopamine transporter binding being reported. However, the paucity of radiotracers for the norepinephrine system has limited investigation of this system in depression, though some tracers for imaging norepinephrine transporter and adrenergic receptors are now under development.

Bipolar affective disorder is also associated with structural brain alterations compared to healthy controls but involving different brain regions to unipolar depression (Selvaraj et al., 2012). Gray matter reductions are seen in temporal cortical regions, prefrontal cortex (in particular the inferior frontal gyrus), and the claustrum, although there is heterogeneity between studies, potentially due to differences in the illness stage of the patients included in the various studies. Increased amygdala activation to emotional stimuli is seen in bipolar affective disorder, both in manic and euthymic patients (Strakowski et al., 2012). In contrast, decreased activation is seen in prefrontal cortical regions including the orbitofrontal and ventrolateral prefrontal cortex. Euthymic patients do not show the same degree of reduced prefrontal activation, suggesting that there may be recovery of prefrontal function. Additionally there is emerging evidence that there is reduced functional connectivity between prefrontal regions and the

amygdala in bipolar affective disorder. Overall, this suggests that a failure of frontal regulation of limbic areas such as the amygdala may underlie the emotional dysregulation that characterizes bipolar affective disorder.

Alzheimer's Disease

Structural Studies

Structural MRI studies have consistently shown structural changes in Alzheimer's Dementia, with cerebral atrophy typically starting in temporal regions, particularly medial temporal areas, and spreading to frontal and parietal regions. At diagnosis, whole brain volume is reduced by ~5%, and reductions in the medial temporal cortex are in the range of 10% (Jack et al., 2008; Johnson et al., 2012). Atrophy begins insidiously in temporal cortex, characteristically beginning in the entorhinal cortex, hippocampus, amygdala, and parahippocampal cortex and gradually progressing in these regions, and extending to other regions. Loss of volume in hippocampal regions is typically in the region of 3–5% per year (Johnson et al., 2012). Studies of people with mild cognitive impairment show that hippocampal atrophy is evident even before the diagnosis of Alzheimer's disease (Jack et al., 2008). MRI assessments of medial temporal region are able to distinguish early Alzheimer's disease from controls with good sensitivity and specificity (>80% in both cases) (Frisoni et al., 2010). Medial temporal atrophy on MRI also shows promise as a marker to identify people who are going to develop Alzheimer's disease in the next year or so, from those with similar mild cognitive impairments who do not go on to develop the disorder in this time frame (Frisoni et al., 2010). It is important to note, however, that while the typical pattern of progressive changes begins in the temporal cortex, atrophy may be seen in other regions and linked to atypical presentations. For example, patients presenting with visual disturbance have been found to show posterior cortical atrophy. Consequently, exclusively focusing on temporal regions may miss some cases. Regional MRI volume has been found to be related to postmortem neuronal counts, suggesting that the volumetric change at least, in part, reflects loss of neurons (Gosche et al., 2002). Furthermore, brain atrophy is directly related to the degree of cognitive impairment seen in the disease (Jack et al., 2002). At the same time that there is gray matter loss, there is widening of cortical sulci and ventricular enlargement (Johnson et al., 2012). Local white matter hyperintensities on MRI have also been reported, although these seem more indicative of vascular dementia and are also seen as part of normal aging.

Functional Cerebral Glucose and Activation Studies

Molecular and functional MR imaging studies have shown brain functional changes in Alzheimer's disease, indicating that the structural changes are accompanied by functional alterations. Cerebral glucose metabolism, as measured by [^{18}F]fluorodeoxyglucose (FDG), is reduced in temporoparietal regions, precuneus, posterior cingulate cortex, and frontal cortex in Alzheimer's disease (Minoshima et al., 1997; Foster et al., 2007). Subsequent fMRI studies have shown alterations in similar regions. In particular, fMRI studies consistently show decreased medial temporal cortical activation during memory tasks in Alzheimer's disease. Findings of fMRI are less consistent in people with mild cognitive impairment, with some studies reporting decreased medial temporal activation, and others increased activation in the same area. This may reflect the stage of illness – with very early phases – but could also be accounted for by differences in the tasks used, and/or performance of the subjects.

Molecular Imaging Studies

As amyloid plaques are a key pathophysiological feature of Alzheimer's disease, considerable effort has gone into developing molecular imaging probes for amyloid. The most extensively used is N-methyl-[^{11}C]2-(4-methylaminophenyl)-6-hydroxybenzothiazole, also known as Pittsburgh compound B (PIB). Elevated [^{11}C]PIB binding is seen in the prefrontal cortex, precuneus, and posterior cingulate of Alzheimer's patients in comparison with controls. Studies have also indicated that amyloid deposition is most active during the early phase of the disease (Engler et al., 2006). However, cognitive impairment does not seem to correlate with extent of [^{11}C]PIB binding, suggesting that while this may be an early marker of the disease process, it is the later consequences of this process that underlie the cognitive dysfunction. [^{11}C]PIB PET imaging appears to be better at detecting mild cognitive impairment and early Alzheimer's disease than changes in cerebral glucose measured with [^{18}F]FDG PET (Klunk, 2011). However, metabolic abnormalities are more regionally specific and may be more closely linked to cognitive deficits (Kadir et al., 2012).

The short half-life of carbon-11 limits the clinical application of [^{11}C]PIB and other radiotracers labeled with carbon-11 to centers with an on-site cyclotron. Fluroine-18 has a much longer half-life, approaching 2 h, which means radiotracers labeled with fluorine-18 can be made at a central site and delivered to a number of regional centers. Consequently, fluorinated tracers for amyloid plaques, such as [^{18}F]flutemetamol, [^{18}F]florbetapir, [^{18}F]florbetaben, and other fluorinated equivalents of [^{11}C]PIB have been developed. One of these, [^{18}F]florbetapir (AMYViD™, Eli Lilly), has recently received FDA approval for the imaging of beta amyloid plaques. [^{18}F]florbetapir scans show very good sensitivity (>90%) and specificity (95%) for amyloid (Yang et al., 2012).

It has been hypothesized that neuroinflammation plays a role in the neuronal loss seen in Alzheimer's disease. Microglia in the brain are typically activated as part of the inflammatory response, and microglial activation is seen in postmortem studies in Alzheimer's disease. The PET tracer [^{11}C]PK11195 indexes the activation of microglia in the brain and has been used to study the neuroinflammatory response in Alzheimer's disease. [^{11}C]PK11195 binding has been found to be elevated in the temporoparietal, cingulate, and entorhinal cortex in Alzheimer's disease, and to correlate with impairments in cognitive performance (Edison et al., 2008). [^{11}C]DED is a PET tracer that measures astrocytic activation that has also been shown to be increased in Alzheimer's disease and in mild cognitive impairment. In fact, [^{11}C]DED binding may be higher in mild cognitive impairment than in Alzheimer's disease, suggesting that astrocytic activation could be an early pathophysiological change in Alzheimer's (Carter et al., 2012).

Molecular imaging may be a useful surrogate marker to monitor treatments for Alzheimer's disease. [^{11}C]PIB PET studies have also been used to evaluate the effect of anti-amyloid treatments, finding that treatment was associated with a reduction in binding (e.g.,: Ostrowitzki et al., 2012). Similarly imaging microglia may help assess the effectiveness of drugs that are targeted toward reducing inflammation in the brain, such as nonsteroidal anti-inflammatory drugs.

Recently it has been recognized that developing and applying imaging to Alzheimer's disease requires developing standardized approaches for the collection of MRI, PET, and other measures, and this has resulted in a number of initiatives to do this and to validate the use of imaging and other biomarkers for the early detection and monitoring of Alzheimer's disease. The Alzheimer's disease neuroimaging initiative (ADNI) is an example of one such initiative that spans research centers around the world. The ADNI has found that combining MRI and PET, with cerebrospinal fluid measures and clinical tests significantly increases the ability to correctly predict conversion to Alzheimer's disease compared with clinical testing alone (Shaffer et al., 2013). This suggests that different imaging modalities provide complementary information, and that a multimodal approach may be most desirable both for research and clinical applications.

Summary

MR and molecular imaging provide *in vivo* measures of a number of aspects of brain structure and function, and enabled them to be linked to clinical measures and outcomes, including changes over time. This is a clear advantage over other approaches such as *postmortem* studies. As such, MR and molecular imaging has already made a major contribution to understanding the biological basis of psychiatric disorders, and it is likely that they will continue to do so. They have contributed to establishing these disorders as brain disorders with distinct neurobiological alterations. In contrast, the direct contribution of these techniques to routine clinical practice is less developed. This is perhaps not surprising given that the technologies are relatively young, the disorders are complex, and there are regulatory and infrastructure barriers that inhibit translation to clinical practice. Initiatives such as ADNI are addressing some of these, and the licensing of [^{18}F] florbetapir indicates that regulatory barriers can be overcome. MR and molecular imaging techniques are becoming increasingly sophisticated and sensitive, and further technological developments, such as combined MR and PET scanners, are likely to contribute to a further refined understanding of the pathophysiology of psychiatric disorders.

Majoritarianism and Majority Rule

Douglas W Rae, Yale University, New Haven, CT, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Majoritarianism and majority rule prove to be an aspiration for regimes in upcoming decades. In comparison with minority rule, majority rule proves to favor political equality and is efficient at coordinating voter preferences to outcomes. In addition, majority rule can trump formal rationality in terms of voting preferences and become skewed when incorporated with proportional representation and other complex institutions. In context to the shifting economic power occurring in the world, many states throughout the world have been slow to incorporate majority rule in their respective states. Through case studies, one sees the struggles and limits of introducing majoritarianism in political regimes.

This article will use 'majority rule' to denote the voting rule requiring $[n + 1]/2$ to carry a decision, and 'majoritarianism' to denote the belief that this rule, and others closely resembling it, are desirable. These ideas may be analyzed by posing four questions:

1. Is majority rule efficiently fair?
2. Does majority rule efficiently match preferences to outcomes?
3. Does majority rule comply with basic requirements of formal rationality?
4. How well do the more complex procedures and electoral systems used in governments match up with majoritarian requirements?

Fairness

In the long history of human governance, majoritarianism has for the most part been trumped but the rule of minorities. Often, these minorities have been elites based on military prowess, land ownership, heredity, or priestly knowledge – whether the priests be religious or, for example, socialist. In capitalist and market societies, elites with major ownership stakes and elites constituted by managerial expertise have in many respects held authority denied to popular majorities (Lindblom, 1977). In other cases, such as the American Constitution of 1789, *generic* minorities threatened by majorities seeking new uses of governmental power are granted the authority to block action. The US system builds in no bias in favor of a specific minority, and it is indeed prejudicial toward all minorities seeking new uses of government. The favorable bias is specific to defensive minorities seeking to preserve existing policy. The overall historical pattern, we may safely conclude, is that most societies have not been governed in majoritarian fashion.

Majoritarianism arises against this background, in major part, as a demand for political equality. Historical demands made for expanded voting rights, across barriers erected on class, religion, gender, and race have played a central role in the democratization of Western nation-states from the beginning. Majority rule is implicit in most of this history. Foremost among the meanings of political equality is the doctrine 'One man (one person), one vote.' This powerful idea links majority rule to the central appeal of popular democracy without specifying exactly the nature of the equality in question. Kenneth May has conveniently formalized this idea with the criterion of *anonymity*: if a decision process yields the result that X is preferred to Y in a given case, it should again do so for every other case in which the preferences of any two blocks of voters of equal size are transposed (May, 1952). Put otherwise, you should always be able to count the votes (and announce a decision) without seeing whose votes they are. Another feature of equality or equity entailed by majority rule concerns the content of the alternates under consideration. Majority rule is formally neutral in its treatment of alternatives. Whether X or Y is the status quo, for example, makes no difference to the counting of votes. Whether X or Y is prolabor, respectful of racial minorities, consistent with the tenets of a prevailing ideology, or consistent with the interests of economic elites – none of these or similar considerations about the alternatives in question will matter under majority rule. This additional requirement of 'neutrality' combines with anonymity in 'May's Theorem' to define majority rule as uniquely best among decision rules, which respond positively and nonrandomly to voter preferences (May, 1952).

The foregoing considerations constitute a strong case for the egalitarian fairness of majoritarianism on an abstractly a *priori* basis. They do not, however, say anything about the fairness of majority rule in specific historical cases where known groups have predictable or announced preferences. Indeed, the neutrality of majority rule toward alternatives implies an embedded incapacity to discriminate in favor of fair, egalitarian, or just policies as against unfair, antiegalitarian, or unjust ones. Majority rule provides no defense against majorities embracing evil. In racially and religiously divided societies, where strong conflicts predictably divide large groups from small ones, this is a crippling disability, which occasions sharp resistance to majority rule. One only needs to think of recent religious and ideological conflict in Iraq, Iran, Egypt, and Turkey to see this point: Where majority and minority are frozen, majority rule becomes a weapon, not a compromise. The time-honored remedies in cases of this sort are *partition* (to produce more homogeneous, less conflictual, and smaller polities), the protection of *minority rights* against specified forms of majority action within each polity, and, of course,

emigration opportunities for members of an afflicted minority. Where some populations enjoy low-cost exit and others do not, even these solutions may seem unfair. The development of civic cultures, which surmount and eventually attenuate conflict is probably superior to any of these more mechanical solutions, but requires historical time and good fortune. It is nevertheless worth noting that even some very hierarchical and undemocratic cultures – India, Japan, quite possibly South Africa – have made great strides in this direction (see, in particular, Shapiro, 2001).

Preference Efficiency

Quite apart from considerations of fairness, a case can be made for majority rule based on its efficiency in matching preferences to policy outcomes. Indeed, it can be shown analytically that all other procedures for making collective decisions are inferior to majority rule in their ability to maximize direct fit between preferences and outcomes (see Rae, 1969; for a critical evaluation, see Mueller, 1989). This applies to other voting rules, rules giving priority to specific types of policy, and all manner of random or arbitrary procedures. Preference-matching efficiency appears most plausible for issues, where the determination of basic policy issues and entitlements is concerned. If decisions entail starkly different stakes for different voters ('Shall we destroy the reader's home?'), nominal matching of preferences to outcomes is obviously inadequate as a criterion. Where decisions offer gains from trade among the rights, so established market and market-like arrangements appear superior on efficiency criteria. Indeed, as Ronald Coase has shown trade can turn any well-defined set of initial rights into a Paretoefficient set of rights on a voluntary basis (Coase, 1960). Insofar as such a process of exchange can be embedded in a voting rule, which would require unanimity for each change of policy (Wicksell, 1896). These market-oriented schemes of course give great leverage to groups and individuals who are privileged by the initial distribution of rights and assets, and are explicitly antimajoritarian for that reason. It must of course be accepted that neither these market-oriented schemes nor majoritarianism can purport to efficient treatment of preferences, which are manipulated, distorted, or subject to intimidation.

Majority Rule and Formal Rationality

It has been well known since the late-eighteenth century that majority rule posses some quirky features, especially when multiple alternatives are considered in one process. Most famous among these is the 'cycle of voting' identified by the Marquis de Condorcet (1785). In the simplest case, we imagine three voters and three alternatives (**Table 1**). In sequential application of majority rule, A defeats B on the strength of voters 1 and 2, B beats C via 1 and 3, yet C tops A via 2 and 3. This violates the axiom of formal rationality known as transitivity, and opens the possibility that control over agenda sequences is tantamount to having control over outcomes. This transitivity requirement, together with others, which tap additional aspects of formal rationality, defines the justly famed Arrow Theorem sowing that all decision procedures, or social welfare functions, may violate the dictates of formal rationality in one way or another (Arrow, 1951).

Table 1 Hypothetical responses of three voters to three alternatives A, B, and C

Voters	*1*	*2*	*3*
Best	A	C	B
	B	A	C
Worst	C	B	A

Majoritarianism in Complex Institutions

Far more important than these formal properties for most purposes is the task of realizing majoritarian aims in complex institutions. The American 'electoral college,' for example, contains the very real potential for reversing national majorities having done so as recently as the fall of 2000. Most single-member electoral systems place an immense premium on spatial distribution of the vote, often giving majority status to parties with well less than majority status in the electorate. Worse yet, where regional parties dominate, as in India, they may fragment outcomes so that nothing close to national majorities are formed. Systems of proportional representation, particularly those based on large districts and exact proportionality, pass the problem of majority formation on to parliaments, and create the opportunity for small parties to exert influence out of all proportions to their size, as with the case of Israel in the 1990s. Most, if not all, legislative procedures, entailing many critical veto points conspicuously violate majority rule. It follows that majoritarianism is less a blueprint than an aspiration.

Conclusion

We live in an era when democratic aspirations have mostly swept the field of direct rivals, particularly among nations that play leading roles in the world economy. Yet in practice, movement toward democratization has been slow, halting, and uncertain in many places. Most of Africa has made little progress, and many key systems from the former Soviet bloc have made minimal progress. China currently displays very less movement toward popular majority politics. Majoritarianism may usefully be seen as one of the key aspirations that should help to shape change and reform in coming decades.

Majorization and Stochastic Orders

Harry Joe, University of British Columbia, Vancouver, BC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The simplest stochastic order is an ordering of 'largeness' on random variables or random vectors; more generally, stochastic orders are orderings that apply to compare random variables or random vectors, or probability distributions or measures. Majorization orderings are orderings of divergence from uniformity and provide a means of proving many inequalities.

Several equivalent forms are given for the stochastic largeness order for random variables, and for measures in a partially ordered space, from which generalizations come from extending one or more of the equivalent forms. Similarly, several equivalent forms are given for vector majorization and generalized majorization for functions on a measure space. Dependence orderings that result from stochastic and majorization orderings are obtained and contrasted. Examples where the orderings overlap, including the Lorenz ordering, are mentioned.

Applications to illustrate the orderings include measures of inequality and diversity, measures of dependence, preference orderings in random utility models for choice, and comparison of risks for portfolios.

Introduction

In a specific context, stochastic orders are orderings of 'largeness' on random variables or vectors: that is, a random variable X is stochastically smaller than another random variable Y or a random vector $\mathbf{X} = (X_1, \ldots, X_d)$ is stochastically smaller than another random vector $\mathbf{Y} = (Y_1, \ldots, Y_d)$ if X tends to take smaller values than Y or the component X_i $(i = 1, \ldots, d)$ of $\mathbf{X}$ tends to take smaller values than the corresponding component Y_i of $\mathbf{Y}$. In a broad sense, stochastic orders are orderings that apply to the comparison of random variables or vectors, or probability distributions or measures, and there have been many such stochastic orders. Here, a few stochastic orders that may be of greater interest in the social and behavioral sciences are summarized. These include orderings of dispersion and dependence.

Majorization orderings are orderings of divergence of a vector or function from uniformity. They are useful as a means of proving many inequalities. The vector majorization ordering applies to vectors of the same length that have the same sum of components. It has been generalized to orderings of functions on measure spaces, and in this context, there are overlaps with stochastic orders.

Stochastic and majorization orderings are defined in Sections Stochastic orders and Majorization Orderings, starting with the simplest forms. Comparisons and contrasts of stochastic and majorization orderings are given in Section Contrast of stochastic and majorization orderings, and illustrative examples of these orderings are given in Section Applications and illustrative examples. The few references that are given provide a guide to research in majorization and stochastic orderings; they include historical perspectives on the orderings – some often cited early references are Hardy-Littlewood-Pólya, Schur, Lorenz, and Dalton for majorization and inequalities, and Lehmann for the simplest stochastic order.

For terminology and notation, increasing (decreasing) is used in place of nondecreasing (nonincreasing), $(z)_+$ denotes $\max\{0,z\}$ over reals, $\overset{d}{=}$ denotes random quantities that are equal in distribution, $F^{-1}(v) = \inf\{x : F(x) \geq v\}$ is the functional inverse of a univariate cumulative distribution function F, and $X \sim F$ denotes a random variable X having the distribution F.

Stochastic Orders

A stochastic order in general means a partial ordering or preordering (the latter need not be reflexive) that compares random variables or vectors, or probability distributions or measures. A stochastic order in a specific sense means the simplest ordering of largeness of random variables; for clarity of terminology, this is referred to as the stochastic largeness order (it is called the usual stochastic order in Shaked and Shanthikumar (2007)). Many stochastic orders generalize this stochastic largeness order in some way. Some main references for this section are Stoyan (1983), Mosler and Scarsini (1993a, 1993b), and Shaked and Shanthikumar (2007).

The definitions of the stochastic largeness orders are given next.

Definition 1 (Stochastic largeness order for random variables.) Let X, Y be random variables with respective distribution functions F, G. X is stochastically smaller than Y, written $X \prec^{st} Y$ or $F \prec^{st} G$, if one of the following equivalent conditions hold.

(1) $\Pr(X > u) \leq \Pr(Y > u)$ for all $-\infty < u < \infty$, or $\Pr(X \leq u) \geq \Pr(Y \leq u)$ for all $-\infty < u < \infty$
(2) $\mathrm{E}[\psi(X)] \leq \mathrm{E}[\psi(Y)]$ for all increasing functions ψ for which the expectations exist
(3) There exist random variables $\hat{X}, \hat{Y}$ on the same probability space such that $\hat{X} \overset{d}{=} X$, $\hat{Y} \overset{d}{=} Y$, and $\Pr(\hat{X} \leq \hat{Y}) = 1$
(4) There exists a monotone kernel $K : \Re \times \Re \to [0, 1]$ (that is, $K(t,\cdot)$ is a distribution function for all $t \in \Re$ and $K(t,u) = 0$ for $u \leq t$) such that $G(u) = \int_{-\infty}^{\infty} K(t,u)dF(t)$
(5) $F^{-1}(v) \leq G^{-1}(v)$ where F^{-1}, G^{-1} are the inverse cumulative distribution functions

Definition 2 (Stochastic largeness order in a partially ordered space.) Let P_1, P_2 be probability measures on a partially

ordered Polish space $(\mathscr{X}, \mathscr{A})$ (usually Euclidean space) with measure ν (usually Lebesgue or counting measure). Let $\prec$ be the partial order on χ; for d-dimensional Euclidean space, the usual partial order is given by $x \prec y$ if $x_i \leq y_i$, $i = 1, \ldots, d$. P_1 is stochastically smaller than P_2, written $P_1 \prec^{st} P_2$, if one of the following equivalent conditions hold.

(1) $P_1(A) \leq P_2(A)$ for all upper sets A (i.e., sets for which $x \in A$ and $x \prec y$ imply $y \in A$)
(2) $\int \psi dP_1 \leq \int \psi dP_2$ for all increasing functions ψ for which the expectations exist
(3) There exist random quantities X_1, X_2 with values in $(\mathscr{X}, \mathscr{A})$ such that $X_1 \sim P_1$, $X_2 \sim P_2$, and $X_1 \prec X_2$ almost surely
(4) There exists a Markov kernel $M: \mathscr{X} \times \mathscr{A} \to [0, 1]$ such that $M(t, \cdot)$ is a measure with support on $\{\mathbf{z} : \mathbf{t} \prec \mathbf{z}\}$ and $P_2(A) = \int M(\mathbf{t}, A) P_1(d\mathbf{t})$ for all $A \in \mathscr{A}$

Many general stochastic orders take the form of (2) with other classes of functions ψ; for example, convex functions, increasing convex functions, and increasing concave functions. Generalizations of the form of (2) are also known as dilation orderings. The class of increasing concave functions leads to second-order dominance. The class of convex functions leads to a dispersion ordering of random variables with the same mean (see Section Contrast of stochastic and majorization orderings), one of many dispersion orderings that have been proposed.

Generalizations for random variables include the hazard rate order, reverse hazard rate order, and likelihood ratio order. These are useful for proving results that are intuitively plausible with a stochastic largeness order; sometimes, the result will not hold or may be much more difficult to prove with $\prec^{st}$.

Definition 3 (Some additional univariate stochastic orders.) Let X, Y be two random variables with respective cumulative distribution functions F, G and densities f, g.

(1) G is larger than F in the likelihood ratio order, denoted by $F \prec^{LR} G$ or $X \prec^{LR} Y$, if $f(x)g(y) \geq f(y)g(x)$ for all $-\infty < x < y < \infty$
(2) G is larger than F in the hazard rate order, denoted by $F \prec^{HR} G$ or $X \prec^{HR} Y$, if $f(x)/[1 - F(x)] \geq g(x)/[1 - G(x)]$ for all $-\infty < x < \infty$
(3) G is larger than F in the reverse hazard rate order, denoted by $F \prec^{RHR} G$ or $X \prec^{RHR} Y$, if $f(x)/F(x) \leq g(x)/G(x)$ for all $-\infty < x < \infty$

It is not difficult to check that $F \prec^{LR} G$ implies both $F \prec^{HR} G$, $F \prec^{RHR} G$, and either $F \prec^{HR} G$ or $F \prec^{RHR} G$ implies $F \prec^{st} G$. Intuitively, these concepts provide different ways of comparing the event of X smaller and Y larger versus the event of Y smaller and X larger. There are multivariate versions of these orderings for random vectors. However, there are also other similar orderings that compare the amount of dependence in multivariate distributions with the set of univariate margins held fixed; these are known as dependence orderings. A basic dependence ordering is given next.

Definition 4 (Concordance ordering.) Let $\mathscr{F} = \mathscr{F}(F_1, \ldots, F_d)$ be the class of multivariate distributions with given univariate margins $F_1, \ldots, F_d$, where $d \geq 2$. Let $F, G \in \mathscr{F}$ with respective survival functions $\overline{F}, \overline{G}$ (defined below). Suppose $\mathbf{X} \sim F$ and $\mathbf{Y} \sim G$. Then G is more concordant than F, written $F \prec^c G$ or $\mathbf{X} \prec^c \mathbf{Y}$, if $\forall \ \mathbf{t} \in \Re^d$,

$$\begin{aligned} F(\mathbf{t}) &= \Pr(X_1 \leq t_1, \ldots, X_d \leq t_d) \\ &\leq \Pr(Y_1 \leq t_1, \ldots, Y_d \leq t_d) = G(\mathbf{t}) \\ \overline{F}(\mathbf{t}) &= \Pr(X_1 \geq t_1, \ldots, X_d \geq t_d) \\ &\leq \Pr(Y_1 \geq t_1, \ldots, Y_d \geq t_d) = \overline{G}(\mathbf{t}) \end{aligned}$$

Note that this concordance ordering compares specific upper sets and lower sets rather than all upper sets as in Definition 2. Hence a distribution is larger in the concordance ordering if the random variables are more likely to simultaneously take large or small values. Other dependence orderings are given in Chapter 9 of Shaked and Shanthikumar (2007) and Joe (1997).

Majorization Orderings

Vector majorization is defined, followed by a general majorization for functions on a measure space. Some main references for this section are Marshall et al. (2011), Arnold (1987), and Joe (1993).

Definition 5 (Vector majorization.) Let $\mathbf{x} = (x_1, \ldots, x_n)$ and $\mathbf{y} = (y_1, \ldots, y_n)$ be vectors in $\Re^n$ such that $\sum_{i=1}^n x_i = \sum_{i=1}^n y_i$. $\mathbf{x}$ is majorized by $\mathbf{y}$ or $\mathbf{y}$ majorizes $\mathbf{x}$, written $\mathbf{x} \prec^m \mathbf{y}$, if one of the following equivalent forms holds.

(1) $\sum_{i=1}^k x_{n-i+1:n} \leq \sum_{i=1}^k y_{n-i+1:n}$, $k = 1, \ldots, n-1$, or $\sum_{i=1}^k x_{i:n} \geq \sum_{i=1}^k y_{i:n}$, $k = 1, \ldots, n-1$, where $(x_{i:n})$, $(y_{i:n})$ are the elements of $\mathbf{x}$, $\mathbf{y}$, respectively arranged in increasing order
(2) $\sum_1^n \psi(x_i) \leq \sum_1^n \psi(y_i)$ for all convex, continuous real-valued functions ψ
(3) $\sum_1^n (x_i - t)_+ \leq \sum_1^n (y_i - t)_+$ for all reals t
(4) There is a doubly stochastic $n \times n$ matrix P (nonnegative matrix such that row and column sums are 1) such that $\mathbf{y} = \mathbf{x}P$
(5) $\mathbf{x}$ is in the convex hull of $\{(y_{i1}, \ldots, y_{in}) : (i_1, \ldots, i_n)$ is a permutation of $(1, \ldots, n)\}$

Majorization is also called the Schur order. There are weak majorization orders that do not require the vector sums to be the same. For example, in (2) of Definition 5, for weak submajorization and weak supermajorization, the class of functions ψ are increasing convex functions or decreasing convex functions, respectively. In economics (e.g., Foster and Shorrocks, 1988), in the context of poverty orderings, majorization is called Lorenz dominance and the second of the weak majorization orderings is called general Lorenz dominance.

Generalizations of Definition 5 have come from generalizations of any one of the equivalent properties. The next definition covers many but not all generalizations of vector majorization. Marshall et al. (2011) unified inequalities through majorization, and although generalized majorization leads to inequalities, inequalities have not always been the motivation for extensions.

Let $(\mathscr{X}, \mathscr{A}, \nu)$ be a measure space. For most applications, $\mathscr{X}$ will be a subset of a Euclidean space, and ν will be Lebesgue measure or counting measure. For a nonnegative integrable function h on $(\mathscr{X}, \mathscr{A}, \nu)$, let $m_h(t) = \nu(\{x : h(x) > t\})$, $t \geq 0$, and let $h^*(u) = m_h^{-1}(u) = \sup\{t : m_h(t) > u\}$, $0 \leq u \leq \nu(\mathscr{X})$; h^* is the (left–continuous) decreasing rearrangement of h.

Definition 6 Let a and b be nonnegative integrable functions on $(\mathscr{X}, \mathscr{A}, \nu)$ such that $\int a d\nu = \int b d\nu$. Then a is majorized by b, written $a \prec^m b$, if one of the following four equivalent conditions holds.

(1) $\int_0^t a^*(u)du \le \int_0^t b^*(u)du$ for all $0 \le t < \nu(\mathscr{X})$

(2) $\int \psi(a)\, d\nu \le \int \psi(b)\, d\nu$ for all convex, continuous real-valued functions ψ such that $\psi(0) = 0$ and the integrals exist

(3) $\int [a-t]_+ \, d\nu \le \int [b-t]_+ \, d\nu$ for all $t \ge 0$

(4) $\int_t^\infty m_a(s)ds \le \int_t^\infty m_b(s)ds$ for all $t \ge 0$

Note that Definition 5 follows from Definition 6 with $\mathscr{X} = \{1, \ldots, n\}$, $a = (a_1, \ldots, a_n)$, $b = (b_1, \ldots, b_n)$, and ν being counting measure. Next a dependence ordering is introduced from majorization to contrast with Definition 4.

Definition 7 (Dependence ordering.) Let $\mathscr{F} = \mathscr{F}(F_1, \ldots, F_d)$ be the class of multivariate densities (with respect to a measure ν) with given univariate margins $F_1, \ldots, F_d$. Suppose F_j has density f_j, $j = 1, \ldots, d$. The (constrained) majorization ordering $f \prec^m g$ of densities $f, g \in \mathscr{F}$ is interpretable as an ordering of dependence. The density $f_I = \Pi_j f_j$ is among those that are minimal in $\mathscr{F}$ with respect to $\prec^m$.

The interpretation of this ordering is different from the concordance ordering in Section Stochastic orders. Densities in $\mathscr{F}$ are larger in this majorization ordering if they diverge more from $f_I = \Pi_j f_j$. Densities for a random vector that almost satisfy a functional relationship are large in the majorization dependence ordering.

Contrast of Stochastic and Majorization Orderings

Some relations between stochastic and majorization orderings are summarized in this section. First consider the case of probability vectors over a finite ordered set of size n, indexed as $\{1, \ldots, n\}$. Let $\mathbf{p} = (p_1, \ldots, p_n)$ and $\mathbf{q} = (q_1, \ldots, q_n)$ be two probability vectors. If $\mathbf{p}$,$\mathbf{q}$ are increasing, then $\mathbf{p} \prec^{st} \mathbf{q}$ and $\mathbf{p} \prec^m \mathbf{q}$ are the same, and if $\mathbf{p}$,$\mathbf{q}$ are decreasing, then $\mathbf{p} \prec^{st} \mathbf{q}$ and $\mathbf{q} \prec^m \mathbf{p}$ are the same. Next, consider probability measures P_1,P_2 that have masses n^{-1} at $x_1, \ldots, x_n$ and $y_1, \ldots, y_n$, respectively. Then (2) of Definition 5 becomes $\int \psi dP_1 \le \int \psi dP_2$, which is of the form of (2) of Definition 2.

An example of an overlap of a stochastic ordering for dispersion and the general majorization ordering is called the Lorenz ordering in Arnold (1987), and other names in mathematics and economics. Since majorization orderings are orderings of divergence from uniformity, this connection is not surprising. In Definition 6, let $\mathscr{X} = [0, 1]$, let ν be Lebesgue measure, and let $a = F^{-1}$, $b = G^{-1}$, where F,G are the respective distribution functions of nonnegative random variables X,Y (with a common finite mean). Since a,b are monotone increasing, the decreasing rearrangements are respectively, $a^*(t) = F^{-1}(1-t)$ and $b^*(t) = G^{-1}(1-t)$. Condition (2) of Definition 6 becomes $\int_0^1 \psi(F^{-1}(t))dt \le \int_0^1 \psi(G^{-1}(t))dt$ or

$$\mathrm{E}[\psi(X)] = \int_0^\infty \psi(s)\mathrm{d}F(s) \le \int_0^\infty \psi(s)\mathrm{d}G(s) = \mathrm{E}[\psi(Y)] \quad [1]$$

for all convex continuous functions ψ. Note that this then implies that $\mathrm{E}(X) = \mathrm{E}(Y)$, by taking $\psi(s) = s$ and $\psi(s) = -s$.

An interpretation is that with a given mean wealth μ, a distribution of wealth F with a constant F^{-1} is most equitable (this corresponds to a mass of 1 at μ) and a distribution F which is larger in the (Lorenz) ordering is less equitable. In this context, the Lorenz curve of a distribution F is given by

$$L_F(s) = \left[\int_s^1 F^{-1}(1-t)dt\right] \Big/ \left[\int_0^1 F^{-1}(1-t)dt\right]$$

$$0 < s < 1$$

This is roughly the complement of the term given in (1) of Definition 6, so a Lorenz curve that is farther below the 45° diagonal is less equitable.

Applications and Illustrative Examples

Majorization and stochastic orderings are interesting to study for their own sake because of interesting mathematical properties, but they have also been widely applied, for example, in operations research, queuing theory, reliability, economics, and many areas of mathematics and statistics. For any ordering, the class of order preserving or isotonic functions is of interest. Member functions of an isotonic class can be used as measures of various types; examples are measures of inequality and measures of dependence.

Example 1. (Measures of inequality and dependence.) Measures of inequality include Gini indices and extensions, poverty indices in economics, and measures of diversity in biology (Marshall et al., 2011; Foster and Shorrocks, 1988). For summarizing data consisting of a mix of categorical and continuous variables, measures of association or dependence are useful. Concordance orderings lead to measures of monotone association like Kendall tau and Spearman rho (Joe, 1990). Constrained majorization orderings lead to measures of divergence from independence like relative entropy measures and uncertainty measures (Joe, 1989).

Example 2. (Random utility models for choice in mathematical psychology.) The setting in random utility choice models is that there is a superset of d items that can be compared in various ways. Suppose the items are assumed to be indexed as $1, \ldots, d$ and $S = \{1, \ldots, d\}$ denotes the index set. Associated with item i is a utility random variable U_i, $i = 1, \ldots, d$; $U_1, \ldots, U_d$ can be independent or dependent. If the U_i are independent, then stochastic ordering results on the U_i lead to preference orderings of various types. The following results are straightforward to prove when the U_i are independent, $U_i \sim F_i$, and there is a zero probability of ties among the U_i,

(1) (i) If $F_k \prec^{st} F_j$, then $p_{jk} = \Pr(U_j > U_k) \ge \frac{1}{2}$ or item j is pairwise preferred to item k. (ii) If $F_k \prec^{st} F_j \prec^{st} F_i$, then $p_{ij}, p_{jk} \ge \frac{1}{2}$ and $p_{ik} \ge \max\{p_{ij}, p_{jk}\}$, or items i, j, k are ordered by strong stochastic transitivity.

(2) If $F_k \prec^{st} F_j$, then $p_{j,S} \ge p_{k,S}$ for S such that $j, k \in S$, where $p_{i,S} = \Pr(U_i > U_\ell, \ell \in S \backslash \{i\})$ is a choice probability of the set S, a subset of $\{1, \ldots, d\}$ with cardinality at least 2. This means the stochastic order implies a preference ordering according to choice probabilities.

(3) Let $r(a_1, \ldots, a_d) = \Pr(U_{a_1} > \cdots > U_{a_d})$, where $(a_1, \ldots, a_d)$ is a permutation of $(1, \ldots, d)$. Let τ_{jk} be a transposition operator so that $\tau_{jk}(a_1, \ldots, a_d)$ is the vector with a_j, a_k transposed. If $F_d \prec^{LR} \cdots \prec^{LR} F_1$, then the items are preference ordered in the strong sense of $r(1, \ldots, d) \geq r(\tau_{jk}(1, \ldots, d))$ for all $1 \leq j < k \leq d$. If the weaker condition $U_k \prec^{HR} U_1$ $(2 \leq k \leq d)$ is assumed, the strongest conclusion is $r(1, \ldots, d) \geq r(\tau_{1k}(1, \ldots, d))$, and if the weaker condition $U_d \prec^{RHR} U_j$ $(1 \leq j < d)$ is assumed, the strongest conclusion is $r(1, \ldots, d) \geq r(\tau_{jd}(1, \ldots, d))$.

These results contrast the strength of conclusions that are possible with various stochastic orders of largeness. Generally, no preference ordering results follow from stochastic ordering assumptions if the U_i are dependent.

Example 3. Comparison of risks for portfolios. Let X, Y be two continuous random variables representing the returns of two portfolios A,B. B is a better portfolio than A if $\mathrm{E}(X) \leq \mathrm{E}(Y)$ and Y is less dispersed than X in some sense. If the ordering of dispersion is taken from the stochastic/majorization ordering in eqn (1), as

$$\mathrm{E}(\psi(\mathrm{Y} - \mathrm{E}[Y])) \leq \mathrm{E}(\psi(\mathrm{X} - \mathrm{E}[X]))$$

for all convex continuous functions ψ, then $\mathrm{E}[u(X)] \leq \mathrm{E}[u(Y)]$ for all increasing concave (utility) functions, and hence this comparison of risk agrees with utility theory with risk averse utilities. See Mosler (1983) for related results.

The examples presented here give an idea of how the orderings have been applied. More recent examples are given in Arnold (2007). The reader can consult the references for many other interesting applications.

Abstract

Born in Cracow, Austrian Poland, Malinowski studied mathematics, physics, and philosophy at the Jagiellonian University before turning to 'primitive sociology' and ethnology in London. Between 1914 and 1918 he conducted three expeditions to Papua, during which he 'discovered' the ethnographic benefits of 'living right among the natives' and mastering their language. Intensive fieldwork was to become the hallmark of British anthropology, and it was largely through Malinowski's mythicized 'heroic' example that it became a rite of passage for entry into the profession. Malinowski spent the interwar years teaching at the London School of Economics, where he was appointed Professor of Social Anthropology in 1927. He promoted the most significant paradigm shift in British anthropology since its creation in the mid-nineteenth century: from the speculatively historical study of cultural traits as 'survivals' to the synchronic study of social 'institutions' within bounded, functioning cultures. Malinowski's 'functionalism' was essentially an appeal for contextualized empirical data purified of historical speculations. It was influential during the 1920s and 1930s and helped him secure Rockefeller funding for his students' research in Africa. His enduring conceptual contributions to anthropology lay in areas such as kinship, marriage, and the family; in magic, myth, and religion; in economic anthropology; and in pragmatic linguistic theory.

A Polish-born anthropologist, Malinowski had a profound influence on the development of British social anthropology between the wars. Under the banner of Functionalism he revolutionized fieldwork methods, contributed to a wide range of academic and public issues, and trained a cosmopolitan cohort of pupils which spread his teachings throughout the world. A passionate, volatile, and sometimes abrasive personality, Malinowski provoked controversy throughout his career; but his intellectual integrity was absolute. He promoted the humanitarian uses of anthropology with entrepreneurial flair, attracting Rockefeller funding to his cause. In addition to his ancestral status as a founder of a cohesive academic discipline, Malinowski's historical legacy in Britain and the Commonwealth was an expanded institutional base for its teaching and practice. In Ernest Gellner's ennobling epithet, Malinowski was 'Anthropologist Laureate of the British Empire.'

A Polish Anglophile

Bronislaw Malinowski was born on 7 April 1884, of noble (*szlachta*) stock in Cracow, capital of the semi-autonomous province of Galicia in the Austro-Hungarian Empire. As a child he lived for several years among local peasantry and, with his mother, took lengthy trips abroad for the sake of his delicate health. To these early experiences of cultural difference Malinowski attributed his vocation to anthropology. He was also inspired by reading James Frazer's *The Golden Bough.*

During Malinowski's youth, Cracow was a vibrant intellectual and artistic center, home of the Modernist movement called Young Poland. His most important early friendship was with the surrealist artist, novelist, and dramatist, Stanislaw Ignacy Witkiewicz. Unable to match his friend's artistic genius, Malinowski resolved to excel in the sciences. At the Jagiellonian University he studied mathematics, physics, and philosophy. His brilliant doctoral thesis, 'On the Principle of Economy of Thought' (1906), was a critique of the positivist epistemology of Ernst Mach; it contained the seeds of Malinowski's later thinking about functionalism (Thornton and Skalnik, 1993).

In 1908–09, during three semesters at the University of Leipzig, Malinowski turned to the study of *Vökerpsychologie* under Wilhelm Wundt and economic history under Karl Buecher. Possessed by 'a highly developed Anglomania,' in 1910 Malinowski crossed the English Channel to enrol as a graduate student in ethnology at the London School of Economics (LSE) in the University of London. The crossing was his Rubicon, and although not granted British nationality until 1931, he was to spend his most productive years in England.

Under the supervision of Edward Westermarck, Malinowski completed his first English book, *The Family Among the Australian Aborigines* (1913), an evaluation of Aboriginal ethnography and a rigorous critique of evolutionist theories. He presented a signed copy to his Polish compatriot, Joseph Conrad, whom he deeply admired.

The Cult of Fieldwork

The dominant paradigm of late-nineteenth century anthropology (or ethnology) was evolutionism, based on the premise that mankind had passed through universal stages of development on the journey from savagery to civilization. A division of labor existed in imperial Britain between armchair theorists (like Frazer) and amateur ethnographers (explorers, missionaries, and colonial officers) who reported from outposts of the Empire.

The professionalization of anthropology began following the Cambridge University Expedition to the Torres Strait of 1898–99 led by the zoologist-turned-anthropologist A.C. Haddon. By 1910 anthropology was being taught at Cambridge, Oxford, and London. It was due to Haddon and his disciples W.H.R. Rivers and C.G. Seligman that Malinowski found an almost messianic cult of fieldwork in Britain. In Seligman's words, 'field research in anthropology is what the blood of martyrs is to the Church.' By the time Malinowski

embarked on his own fieldwork, at least a dozen students of Haddon and his colleagues had preceded him.

World War One broke out just as Malinowski arrived in Australia. Although cut off from his English funds and under suspicion as an 'enemy alien,' he was permitted entry to Papua (ex-British New Guinea) to conduct his research. His apprentice fieldwork was among the Mailu of the south coast, whence Seligman had directed him to fill a gap left by his own ethnographic survey of Papua a decade earlier. After five busy months, Malinowski returned to Australia where he dashed off *The Natives of Mailu*, a conventional ethnographic report (Young, 1988). In June 1915 he returned to eastern Papua with Australian funding for a second spell of fieldwork. Supposedly en route to another field site, Malinowski visited Kiriwina, the largest of the Trobriand Islands, about which Seligman had already reported comprehensively in *The Melanesians of British New Guinea* (1910). For various reasons Malinowski's visit to Kiriwina evolved into a sojourn of 10 consecutive months, followed by a second period of 10 months in 1917–18. Although his movements were restricted by the colonial authorities, Malinowski was not, as his popular legend had it, 'interned' in the Trobriands.

He had learned in Mailu that the richness of his data was a function of the time he had spent living in the village, shunning the company of fellow Europeans and observing everyday life at first hand. It was also imperative to master the local language well enough to have unmediated access to one's subjects. Under the rubric 'the intensive study of limited areas,' such precepts of method had been advocated by Haddon and Rivers during the previous decade, but they had not been put into proper practice until Malinowski's work in Kiriwina.

Thus, the innovative breakthrough his fieldwork effected was based on the simple expedient of living in the same location for many months and probing for information in the vernacular. This method of 'total immersion' encouraged a more intimately interactive style of ethnography, permitting an empathetic understanding which went beyond mere recording. The fieldworker could begin to know another culture from within: 'the final goal' of the ethnographer is 'to grasp the native's point of view ... to realize *his* vision of *his* world' (Malinowski, 1922: p. 25). 'Participant observation' was to become the catch-cry of his pupils' generation. It still remains the hallmark of anthropological fieldwork. Professionally, it was prolonged and intensive fieldwork, with its loneliness and hardship, that stamped the new breed of anthropologist (Stocking, 1995: Chap. 6).

Trobriand Man as Exemplar

Malinowski was criticized for making his Trobri-anders the measure of mankind, but he did so persuasively as Trobriand Man was introduced into the controversies of the day. On close inspection, this exemplar of the Savage was not so very different from Civilized Man. He was demonstrably rational and technologically competent, morally and aesthetically sensitive: an equal, therefore, and not (as imperialists and evolutionists would have it) a benighted inferior. He believed in magic, certainly, but he used it only in situations where technology could not guarantee an outcome. 'Magic helps those who help themselves.' Magic was a tool to which men resorted when the desired end of any enterprise was in doubt. This instrumental, pragmatic view of magic was typical of Malinowski's functionalism.

In 1922 Malinowski published his first Trobriand classic, *Argonauts of the Western Pacific*, which set British anthropology firmly on a new course (Malinowski, 1922). It was a richly textured study of *kula*, the circuitous ceremonial exchange of shell valuables which linked the Trobriands to neighboring archipelagoes. Malinowski's combination of ethnographic observation, methodological prescription, and literary romanticism was vivid and compelling. An enthusiastic preface by Sir James Frazer ensured *Argonauts'* successful launch.

With *Crime and Custom in Savage Society* (1926), a little book on 'the seamy side' of Trobriand law, Malinowski pioneered the study of political and legal anthropology. The following year, *Sex and Repression in Savage Society* set a cat among the Freudian pigeons by contesting the claim that the Oedipal Complex was universal (Malinowski, 1927). Malinowski argued that in the matrilineal Trobriands it was the mother's brother, not the father, who was the hated authority figure; likewise, it was the sister, not the mother, who was the main object of a boy's incestuous desire. The debate continues.

The Sexual Life of Savages (Malinowski, 1929) was a detailed study of Trobriand courtship, marriage, and domestic life; it was also a covert attack on sexual prudery and hypocrisy, and in the changing mores of the period it had a liberating appeal.

Malinowski's last Trobriand ethnography, *Coral Gardens and their Magic* (1935), dealt exhaustively with horticultural practices and their ritual accompaniments, with land tenure and its politics, and with the language of magic. The two-volume work was a triumph of thick description and a baroque monument to its author's functional method.

Malinowski fancied that his monographs did for anthropology what Joseph Conrad's novels had done for English literature. It is true that through these and many other writings, Malinowski's Trobrianders came to be known as one of the best-documented 'primitive' peoples in the world. Subsequent generations of anthropologists have reinterpreted his material in the light of different theories – the most flattering compliment posterity can pay to any ethnographer.

Functionalism

The paradigmatic theory that informed Malinowski's Trobriand monographs was functionalism. As an heuristic method which guided fieldwork, functionalism was an appeal for contextualized empirical data purified of historical speculations. Malinowski urged ethnographers to look for the use of a custom (or institution) in the present, so as to determine the part it played in the integral working of a society or culture. This would give the clue to its meaning and the explanation for its existence, one that (in contrast to the speculative explanations of 'antiquarian' anthropologists) was concretely based on empirical observation. Although functionalism was demonstrably deficient when applied to societies undergoing rapid social change, as a 'clinical' method it was immensely influential during the interwar years. The promise it offered

'practical' or applied anthropology in African colonies enabled Malinowski to secure, through the sponsorship of the International African Institute, Rockefeller funding for his students' fieldwork.

His theory of language was based on the premise that function determined form. 'Primitive' language was 'a mode of action' rather than a 'countersign of thought.' Much speech is 'phatic' (agreeable social noises such as 'How are you?') or instrumentally pragmatic, meaningful only in its 'context of situation.' Malinowski foreshadowed Ludwig Wittgenstein's axiom 'do not ask the meaning but the use.'

As grand theory, Malinowski's functional view of culture as an apparatus for the satisfaction of human needs was born out of Machian empiricism, confirmed by Jamesian pragmatism, and blessed by the Durkheimian tenet that culture was *sui generis*. Malinowski's 'scientific theory of culture' (1944a) was built on the premise that man's biological heritage provided the ground plan for all cultures; basic (or primary) needs such as reproduction and derived (or secondary) needs such as education yielded similar cultural solutions, the universal form of which was the family. In a nutshell, he argued (a) that function determines the form of cultural entities; (b) that the essential element of the science of culture is the institution; and (c) that institutions must ultimately be defined in relation to the biological needs they satisfy. As formal theory, then, functionalism explained culture in an instrumental and reductionist fashion. The schematic, utilitarian form in which he presented this theory gained few adherents and it was soon forgotten.

Teacher, Pundit, and Propagandist

Malinowski's rise to eminence at the LSE had been rapid: from Lecturer in 1923, Reader in 1924, to foundation Professor of Social Anthropology in 1927. The mode of teaching he favored was the seminar. In Socratic fashion, he deployed wit, erudition, and 'intellectual shock tactics' to provoke thoughtful argument. His electrifying seminar became a legend during the 1930s, engaging his brightest pupils and attracting from every continent students of cognate disciplines. The multiethnic roll-call of his pupils would fill a page, but among the most eminent were Raymond Firth, Edward Evans-Pritchard, Ashley Montagu, Isaac Schapera, Audrey Richards, Camilla Wedgwood, Meyer Fortes, Paul Robeson, Siegfried Nadel, Lucy Mair, Reo Fortune, Ralph Bunche, Ian Hogbin, Jomo Kenyatta, Talcott Parsons, Gregory Bateson, Edmund Leach, and Phyllis Kaberry.

Despite his fragile health, Malinowski was a ferociously hard worker who mustered others to his aid. He employed servants at home, dictated most of his writings to stenographers, and employed pupils as long-suffering research assistants. Until she was tragically incapacitated by multiple sclerosis, Elsie, his Australian-born wife, served him as a loving critic and secretary. Together with their three daughters they spent summers at the family villa in the South Tyrol, where pupils often visited to walk and talk (Wayne, 1995).

In tandem with his academic activities, Malinowski performed the role ofpublic intellectual, disseminating progressive views on marriage, the family, and sex education. He lectured missionaries and colonial officers; he gave BBC talks on religion; he actively supported the British Social Hygiene Council and Mass Observation. More importantly, he served on the board of the International African Institute for which he devised a field training program. In 1934 he visited several of his pupils in South and East Africa before conducting some fieldwork of his own in Tanganyika.

Malinowski had lectured widely in the United States in 1926, 1933, and 1936, and he returned for a sabbatical year in October 1938. When war broke out in Europe he was advised to remain in America for the duration. He taught at various universities, anxious to secure a permanent position. As 'war work' he embarked on a lecturing and writing campaign of propaganda (his own term) to convince Americans of the need to fight Hitler. Of all the honors he received he valued most the distinction the Nazis conferred upon him by burning his books. His opposition to totalitarianism was categorical and he wrote passionately against it in *Freedom and Civilization* (Malinowski, 1944b).

During the summers of 1940 and 1941 Malinowski conducted fieldwork in the Oaxaca Valley of Mexico with his new wife and a Mexican assistant. This fieldwork did not match the exacting standards he had set in the Trobriands. Just before his sudden death of a heart attack on 16 May 1942 in New Haven, CT, Malinowski was appointed to a permanent professorship at Yale University and elected President of the Polish Institute of Arts and Sciences in New York.

Malinowski's Legacy

Malinowski bequeathed a controversial legacy. He did more than anyone else of his time to establish a cohesive (even 'clannish') school of anthropology with a unique academic profile. But the year he left for America was the year A.R. Radcliffe-Brown returned to England to create a rival school at Oxford. The latter's more Durkheimian and sociologically austere version of functionalism (known as structural functionalism) attracted many of Malinowski's erstwhile disciples. Radcliffe-Brown dominated British social anthropology during the following decade.

In 1957, a dozen of Malinowski's pupils published a Festschrift which critically evaluated his contribution to different subfields. While conceding that he was an incomparable ethnographer, the majority verdict was that Malinowski was a flawed and inconsistent thinker who had failed to grasp the analytical priority of 'systems' and 'structures.' It thus became a cliche of disciplinary folk history that Malinowski was a brilliant ethnographer but a mediocre theoretician.

This view justified neglect of his work until the late 1960s, when, abetted by Raymond Firth, Malinowski's successor at LSE, the pendulum swung from a theoretical preoccupation with structure to the analysis of process and event. Malinowskian 'methodo logical individualism' became respectable again through decision-making analysis and transactional anthropology. Meanwhile there was a rapprochement between British social and American cultural anthropology as their research agendas converged. American anthropologists had always been receptive to Malinowski's field methods, and eventually the kind of fieldwork they conducted became

indistinguishable from that of their British and Commonwealth colleagues.

In 1967, Malinowski's widow published his personal field diaries. They were an embarrassment to many of his pupils and Raymond Firth's preface to the book is an exercise in damage control. Malinowski's agonized musings on the alienation he experienced in the field put the lie to the effortless rapport he was believed to have enjoyed with Trobrianders. His diaries exacerbated, if not precipitated, a moral and epistemological crisis of anthropology during the 1970s, when global decolonization was turning attention to the exploitative aspects of the discipline and its dubious historical role as a handmaid of Imperialism.

The occasion of Malinowski's centenary celebrations in 1984 produced another round of evaluations, the most notable being a collection of essays by Polish scholars. They not only rehabilitated Malinowski's reputation in his homeland, but painstakingly examined his theories in the light of his Polish roots. He was declared a scientific humanist and rationalist, a romantic positivist and political liberal who belonged in the mainstream of modernist European thought (Ellen et al., 1988).

In America the diaries stimulated fresh debates on the assumptions underlying Malinowskian fieldwork and ethnographic representation. Postmodernists appropriated Malinowski for their own rhetorical ends in deconstructing ethnographic authority. To an ironic degree, however, he had pre-empted some of their concerns by the humanistic strain in his work and, except when promoting his 'science' for institutional support on behalf of 'practical anthropology,' he was by no means a naive positivist. Nor was he a 'romantic primitivist' as some critics have charged, despite the Frazerian echoes in his earliest monographs. Fully 50 years before postmodernists deconstructed exoticism, Malinowski had come to the view that anthropology romantically 'over-sensationalized' differences between cultures, and he questioned its fascination with 'freakish' customs such as polyandry, widow burning, and headhunting.

Despite the fragmentation of socio-cultural anthropology at the millennium, Malinowski's fruitful concepts can be detected in almost every subfield, and his legacy persists wherever ethnography is practiced. His name is indelibly linked with Melanesia, but it appears too in anthropological writings from countries as far-flung as Mexico and China, Italy and New Zealand, and India and Ireland. A protean, cosmopolitan-ancestral figure, then, Malinowski continues to fascinate his intellectual descendants.

Abstract

Thomas Robert Malthus (1766–1834) was brought up in the ideology of progress, but made a complete break with progressive thought with his *Essay on the Principle of Population* (1798), in which he argued that it is useless, even dangerous, to provide relief for the poor, as this encourages them to reproduce. The success of this work provoked a heated discussion, obliging Malthus to expand and elucidate his ideas on population. This resulted in a second *Essay* (1803), markedly different from the first. This work established Malthus's lasting reputation; he was appointed to a chair in political economy – the first of its kind in Europe – and elected a member of the Royal Society. In 1820, he published another major work: *Principles of Political Economy*. Malthus's theory soon became known on the continent, particularly in France and Germany, but not without misconceptions or misinterpretations. Most of his opponents have only taken up a caricatural model according to which population always increases in a geometrical progression, while the means of subsistence only increase in an arithmetical progression. In fact, Malthus referred only to tendencies: demographic growth is always checked, be it preventively or positively. In the first *Essay*, these checks were identified as misery (in the wider sense) and vice; in the second *Essay*, Malthus introduced the notion of moral restraint (meaning late marriage). All this was embedded in Malthus's moral and theological reflection on progress and Providence; but the *Principle of Population* also implied pessimistic views on poverty and state assistance, meaning that Malthus's reputation – among socialists and progressivists at least – was permanently tarnished. This perception was quite unjustified, since Malthus was a liberal member of the Whig Party and in favor of reform. Malthus's intellectual legacy was extremely varied. On the economic level, the theory of effective demand, which he introduced in the *Principles*, was a lasting success; on the political level, the very term 'Malthusian' was coined as early as 1822 by Francis Place, who proposed a much easier and more effective method of checking population growth than moral restraint: the limitation of births within marriage. It is in this form, representing a complete break with Malthus' theory, that neo-Malthusianism became established in the nineteenth century, gaining wide acceptance after the Second World War, even at the United Nations.

The passions aroused even today by the name of Malthus bear witness to the eminent position – almost equal to that of Marx – which he still occupies in the history of ideas.

An Unspectacular Life

Thomas Robert Malthus was born on 13 February 1766, in 'The Rookery' in Dorking, near Wooton, Surrey, England. His father, Daniel Malthus, was a prosperous, brilliant, and educated man, a convinced progressive who corresponded with Voltaire and particularly with Rousseau, who visited him on March 9 of the same year.

Very much taken with new ideas, Daniel Malthus brought up his son in accordance with the precepts of *Émile*, and put him in the charge of two dissentient intellectuals: Richard Graves (1715–1804), who had to leave Cambridge as a result of a misalliance, and Gilbert Wakefield (1756–1801), a former pastor who taught classical literature at Warrington Academy and was imprisoned in 1799 for writing that the poor would have nothing to lose from a French invasion. To crown this educational career, Malthus, who had been admitted to Jesus College, Cambridge, in 1784, became a pupil of William Frend (1757–1841), who was dismissed from the university in 1793 for publishing three pamphlets against the Church. It was perhaps Frend who aroused Malthus' interest in economics and demography (Petersen, 1979).

In 1788 Malthus took holy orders, in 1793 he was elected a fellow of Jesus College and became rector of Oakwood Chapel (Surrey), 12 or 13 km from the village of Albury, where his father Daniel had settled in 1787. Some years later, he wrote a first essay entitled *The Crisis, a View of the Recent Interesting State of Great Britain, by a Friend of the Constitution*. No publisher could be found for this work, however, and only extracts – published after Malthus' death by his friends William Empson and William Otter – survive (Otter, 1836). These reveal a very politically correct Malthus, an advocate of the provision of state assistance at home for those not capable of securing their own livelihood.

Two years later Malthus' polemic pamphlet was published, marking a complete break with the progressive ideas of his entourage: *An Essay on the Principle of Population as it Affects the Future Improvement of Society; With Remarks on the Speculations of Mr. Godwin, M. Condorcet and Other Writers*. The essay was published anonymously, but Malthus was recognized immediately as its author. The pamphlet established Malthus' name, but its central thesis, which was expressed with an apparent scientific detachment, that it is useless, even dangerous, to provide relief for the poor as this encourages them to reproduce, created a scandal.

Malthus, described by all those who met him as a gentle, courteous, sincere, and sensitive man, was thus drawn into a heated and interminable discussion, obliging him to expand and elucidate his ideas on population.

After traveling with his Cambridge friends to Scandinavia (1799), France, and Switzerland (1802), and producing a new essay on price increases (*An Investigation of the Cause of the Present High Price of Provisions* 1800), thus demonstrating his talents as an economist, Malthus published a new book in 1803. This is regarded as a second edition of the 1798

Essay; and indeed entire chapters were taken from the first edition, but the 1803 edition differs fundamentally with respect to its complete title (*An Essay on the Principles of Population, or a View of its Past and Present Effects on Human Happiness with an Inquiry into our Prospects Respecting the Future Removal or Mitigation of the Evils which it Occasions*), its (fourfold) length and, above all, its content, now constituting moral and sociological reflections on population growth. Even during the author's lifetime, the new *Essay* was revised four times with additions and corrections.

In April 1804 Malthus, now 38, married his cousin Harriet Eckersall at Claverton, near Bath. Within four years, she had given birth to one son and two daughters (Petersen, 1979).

In 1806 he was appointed professor of history and political economy at the East India Company's college, which opened at Hertford before moving to Haileybury (Hertfordshire) several years later. He held this chair in political economy – the first of its kind – until his death, and publicly defended the college when its existence was jeopardized (Petersen, 1979).

For 14 years, Malthus produced little more than a variety of pamphlets – particularly on the importance of grain – but with the five successive editions of his second *Essay* he established such a reputation that he was elected a member of the Royal Society (1819), a corresponding member of the Royal Society of Literature (1824), and later an associate member of the *Académie des Sciences Morales et Politiques* and the Royal Academy of Berlin (1833). In 1821 he was one of the founder members of the Political Economy Club and, in the year of his death, of the Royal Statistical Society.

In 1820 Malthus's second *magnum opus* was published: *Principles of Political Economy Considered with a View to Their Practical Application*. Being of a concrete nature, it was opposed to the more systematic and dogmatic views of David Ricardo (Keynes, 1939).

After this, there is little to report apart from the publication of an article entitled 'Population' in the *Encyclopaedia Britannica* (1824) and further trips to the continent and to Scotland. Having gone to Bath to spend Christmas with his family, Malthus died of a heart attack on 29 December 1834, at the age of 68. His grave is to be found in Bath Abbey.

Malthus's Contribution to the Sociology and Economy of Populations

What the general public, nonspecialists and, regrettably, many historians and economists have taken up of Malthus' theory is a caricatural model according to which population always increases in a geometrical progression, while the means of subsistence only increase in an arithmetical progression, thus making it necessary to limit births by all possible means.

In fact, Malthus' theory went through a complex evolutionary process, developing from one work to the next. His central ideas, however, were already present in the 1798 *Essay*.

Originally, this first *Essay* was merely a philosophical pamphlet intended as a criticism of the utopian optimism of Godwin and Condorcet. The author's main aim was to undermine the theory that it was possible for man and society to progress. In the conclusion to chapter VII, he resumes his arguments as follows:

> Must it not then be acknowledged by an attentive examiner of the histories of mankind, that in every age and in every state in which man has existed, or does now exist,
> –That the increase of population is necessarily limited by the means of subsistence.
> –That the population does invariably increase when the means of subsistence increase. And,
> –That the superior power of population is repressed, and the actual population kept equal to the means of subsistence by misery and vice (Malthus, 1798).

In the preface, Malthus states that "(t)he following Essay owes its origin to a conversation with a friend (very probably Daniel Malthus, the author's father, who was to die two years later, taking his generous ideas and fabulous illusions with him to the grave) on the subject of Mr. Godwin's Essay on avarice and profusion in his Enquirer."

The discussion started the general question of the future improvement of society, and the author at first sat down with an intention of merely stating his thoughts to his friend upon paper in a clearer manner than he thought he could do in conversation. But as the subject opened upon him, some ideas occurred, which he did not recollect to have met with before; and as he conceived that every the least light on a topic so generally interesting might be received with candor, he was determined to put his thoughts in a form for publication (Malthus, 1798).

A generation gap? Certainly, but one which only acquired its full significance from the fact that it occurred at a turning point in history. Indeed, in the first chapter, Malthus refers to "the new and extraordinary lights that have been thrown on political subjects, which dazzle, and astonish the understanding; and particularly that tremendous phenomenon in the political horizon the French Revolution, which, like a blazing comet, seems destined either to inspire with fresh life and vigour, or to scorch up and destroy the shrinking inhabitants of the earth, have all concurred to lead many able men into the opinion that we were touching on a period big with the most important changes, changes that would in some measure be decisive of the future fate of mankind."

Malthus was well aware of the disillusionment and skepticism engendered by this first historical assault on the prevailing ideology: "The view which he has given of human life has a melancholy hue; but he feels conscious that he has drawn these dark tints, from a conviction that they are really in the picture; and not from a jaundiced eye, or an inherent spleen of disposition" (Malthus 1798).

In this first essay, Malthus's argument is backed up by few concrete examples but for a brief examination of the different stages of civilization through which humanity has gone (Chaps. III and IV), case studies of England (Chap. V), the new colonies (Chap. VI), and a note on the speed with which even the old states recovered from the ravages of war, pestilence, famine, and natural catastrophes. The main part of the work (Chaps. VII–XV) is devoted to a rebuttal of the ideas of Wallace, Condorcet, and particularly Godwin, who had just published the third edition of his philosophical treatise *An Enquiry Concerning Political Justice and Its Influence on General Virtue and*

Happiness (Godwin 1798). However, two chapters (Chaps. XVI and XVII) initiated the criticism of Adam Smith's economic theory, and two others (Chaps. XVIII and XIX, both omitted from the second *Essay)* seem to provide the key to Malthus' system of values.

In the tradition of the Scottish moralists – particularly Abraham Tucker – whose influence he had been exposed to at Cambridge, Malthus came to believe that the constant pressure that misery exerts on man leads to a conception of life in which hope is directed towards the afterlife (Tucker, 1776, in Dupaquier and Fauve-Chamoux, 1983). In contrast to these moralists, however, Malthus refused to see life on earth as a trial, but as 'a process necessary, to awaken inert, chaotic matter into spirit; to sublimate the dust of the earth into soul; to elicit an aethereal spark from the clod of clay (Malthus, 1799).

Malthus went on to elaborate a theory of stimulation which anticipated that of Toynbee: "To furnish the most unremitted excitements of this kind, and to urge man to further the gracious designs of Providence by the full cultivation of the earth, it has been ordained that population should increase much faster than food ... consider man, as he really is, inert, sluggish and averse from labour, unless compelled by necessity ... we may pronounce with certainty that the world would not have been peopled, but for the superiority of the power of population to the means of subsistence … . The principle according to which population increases, prevents the vices of mankind, or the accidents of nature, the partial evils arising from general laws from obstructing the high purposes of the creation. It keeps the inhabitants of the earth always fully up to the means of subsistence; and is constantly acting upon man as a powerful stimulus, urging him to the further cultivation of the earth, and to enable it, consequently, to support a more extended population" (Malthus, 1798).

The Malthus of 1798 was a moralist, sociologist, and demographer, rather than an economist. He had begun to reflect on aspects of this domain, however. In his first *Essay*, he criticized Adam Smith's idea that any increase in revenue and capital leads to an increase in the size of the wage fund designated for the upkeep of the labor force, and referred to cases in which increasing wealth had in no way improved the living conditions of poor workers. On the same lines, addressing the problem of how correctly to define the wealth of a nation, he criticized the Physiocrats, and contended that the work of craftsmen and workers was productive for the individuals themselves, although not for the nation as a whole.

Malthus did not return to these thoughts in the first three editions of the second *Essay*, but the gradual development of his theory can be seen in *An Investigation of the Cause of the Present High Price of Provisions* (1800), his teachings at the East India Company's college, his article *Depreciation of Paper Money* in the *Edinburgh Review*, and his publications *Pamphlets on the Bullion Question* in the same journal, *Observations on the Effects of the Corn Laws* (1814), *Principles of Political Economy* (1820), and *Definitions in Political Economy* (1827).

How can Malthus' approach to economics be summed up in a few words? It is not a coherent, systematic and immutable whole: 'Yet we should fall into a serious error,' he wrote in the *Principles*, "if we were to suppose that any propositions, the practical results of which depend upon the agency of so variable a being as man, and the qualities of so variable a compound as the soil, can ever admit of the same kinds of proof, or lead to the same certain conclusions, as those which relate to figure and number" (Malthus, 1820).

Overall, Malthus adhered to the principles of the classical school, but was critical of the idea that human needs and desires are indefinitely and immediately expansible. According to Joseph-J. Spengler, Malthus argued that population growth is conditioned by the 'effective demand' for labor, and not primarily by the productive capacity. "Such a demand in fact only tends to occur when adequate moral and political conditions coincide, when the social structure is flexible, the landed property correctly divided and commerce active, when a sufficient number of individuals are willing and able to consume more material wealth than they have produced, and when human beings are strong enough to compensate for the inelasticity of the demand for goods and services in terms of effort" (Malthus, 1798).

It is primarily where demography, sociology, and morality are concerned that the second *Essay* marks a development in Malthus' thought.

In his first *Essay*, Malthus barely touched upon demographic science or political arithmetics as it was known at the time. He knew his Hume, Wallace, and Price, cited King, Short, and Süssmilch, but, with the exception of the latter, overlooked the work of foreign scholars. He contented himself with rough calculations on 'the unhealthy years' and the relationship between the number of births and the number of burials. In his second *Essay* on the other hand, he devoted one chapter to the fertility of marriages, another to the effect of epidemics on population movements, and a third to emigration though this cannot be defined as demographic analysis.

Where sociology is concerned, the core of the second *Essay* consists in an analysis of the checks to population in the lowest stage of human society (Book I, Chap. III), among the American-Indians (Chap. IV), in the islands of the South Sea (Chap. V), among the ancient inhabitants of the North of Europe (Chap. VI), among modern pastoral nations (Chap. VII), in different parts of Africa (Chap. VIII), in Siberia (Chap. IX), in the Turkish dominions and Persia (Chap. X), in Indostan and Tibet (Chap. XI), in China and Japan (Chap. XII), among the Greeks (Chap. XIII), among the Romans (Chap. XIV), and in the various states of modern Europe: Norway, Sweden, Russia, middle parts of Europe, Switzerland, France, England, Scotland, and Ireland (Book II, Chaps. I–VIII).

For the most part, the sources of these reflections have been located (cf. the contributions of M. Godelier, N. Broc, and J. Stagl in Fauve-Chamoux *Malthus hier et aujourd'hui* (1984), and Malthus's interpretations – especially those concerning primitive societies – have been discussed, but the central element here is the new way of approaching the issue. Malthus, thus, emerges as one of the pioneers of the sociology of populations. It is on the moral and political level, in particular, that Malthus's theory is completed, confirmed, and substantiated in the second *Essay* and the successive editions.

In the first *Essay*, he asserted that the reproductive power of the human population could only be checked by misery and vice, the word 'misery' being used in the broad sense, and 'vice' in the sense of sexuality being deviated outside of the institution of marriage. While he did not yet use the term 'moral

restraint,' he further indicated that the pressure of providing for a family operates to varying degrees in all classes of society, and termed this a 'preventive check' in opposition to the 'repressive check' of misery.

In the second *Essay*, he introduced moral restraint explicitly as another of the checks preventing the population from increasing beyond the limits of the means of subsistence. Two chapters of book IV are devoted to moral restraint, the obligation to practice this virtue, and the effect this would have on society.

All this was embedded in Malthus's reflections on the lot of the poor and the principle of aid. While in 1796 (*The Crisis*) Malthus had defended the principle of state assistance at home, 2 years later in the *Essay* he asserted not only that the immense sums of money collected in conjunction with the poor laws would not improve the living conditions of paupers, but that 'they have spread the general evil over a much larger surface,' having encouraged the poor to reproduce.

In the *Essay* of 1803, Malthus went even further. In order to illustrate the idea that paupers had no right to aid, he conceived the famous analogy of the banquet, in which the theme was carried to a ridiculous extreme. This offending passage was cut out of following editions, but was unearthed in 1820 by Godwin, who had undertaken, rather late in the day, to refute the Malthusian doctrine (Godwin, 1820). In this, he was followed by most of the later writers, either in good faith or otherwise.

Petersen, in his famous book *Malthus Reconsidered* (1979), shows why Malthus is termed reactionary by ideologists, and points out the injustice of this accusation: "Malthus was an active member of the Whig Party, and the social reforms he advocated – in addition to the crucial one of universal schooling – included an extension of the suffrage, free medical care for the poor, state assistance to emigrants, and even direct relief to casual labourers or families with more than six children; similarly, he opposed child labour in factories and free trade when it benefited the traders but not the public. Apart from such details he was an honest and beneficent reformer, committed throughout his life to the goal that he shared with every liberal of his day – the betterment of society and of all the people in it."

The Impact of Malthus and Malthusianism

Malthus's theory soon became known on the continent, particularly in France and Germany. In France, while the *Essay* of 1798 was not translated until 1980 (by Vilquin), parts of the *Essay* of 1803 were presented in the *Bibliothèque Britannique* as early as 1805 by the Genevian Pierre Prévost, who was also responsible for the translation of the third edition in 1809. The *Principles of Political Economy* appeared in French in the year of their English publication. In Germany, Malthus was translated several times from 1806 onwards. In the rest of Europe (Italy, Spain, Russia), Malthus's works were not translated until the second half of the nineteenth century, but as philosophers and economists read them in English, French, and German, they were much discussed (Fauve-Chamoux, 1984).

In view of the frequency of misquotations, mis-readings, second-hand references, silly remarks, and invectives accumulated by these commentators, however, one cannot help but wonder whether the majority of them, even Karl Marx, had really read Malthus's publications.

The most common misconception – particularly among economists – is that Malthus contended that the population really does increase in geometrical progression while the means of subsistence increase in arithmetic progression. In fact, Malthus referred only to tendencies, and refused to allow his theory to be reduced to the simplistic conclusion that population is regulated by subsistence.

An associated misconception casts Malthus as an enemy of demographic growth. In fact, as early as 1805 he made it quite explicit that "It is an utter misconception of my argument to infer that I am an enemy to population. I am only an enemy to vice and misery, and consequently to that unfavourable proportion between population and food which produces these evils." This misconception was soon so widespread that the adjective 'Malthusian' was coined to describe not only the practice of restricting births but, in the last half of the nineteenth century, the practice of limiting economic production.

As a rule, socialists have poured scorn on Malthus for his liberal ideas and his skepticism with respect to social intervention policies. In attacking Godwin, he had undermined the very basis of utopian socialism. This resulted in a vigorous, if somewhat delayed, reaction from Godwin himself (Godwin, 1820), to which Malthus responded the following year in the *Edinburgh Review*.

This debate came to a head in 1839, when Marcus (1939) accused Malthus of advocating the asphyxiation of 'surplus' newborns, a myth which was taken up and popularized in France by Leroux (1839) with expressions such as 'the somber Protestant of sad England' and 'the selfish defender of the propertied classes.' Karl Marx, champion of invective, is every bit as dismissive, denouncing Malthus as 'superficial,' 'a professional plagiarist,' 'the author of nonsense,' 'the agent of the landed aristocracy,' 'a miserable sinner against science,' 'a paid advocate,' 'the principal enemy of the people,' etc. (cf. Michelle Perrot, *Malthusianism and Socialism* in Dupaquier and FauveChamoux 1983).

However, most socialists apart from Marx agree that there is a connection between overpopulation and misery, but distance themselves from Malthus with respect to the proposed causes and remedies. The most serious discussion of Malthus's theories is to be found in the work of Karl Kautsky (Kautsky, 1880). When neo-Malthusianism came to the fore at the end of the nineteenth century, however, socialist criticism once more became more radical. Where his doctrines are concerned, Malthus has had a large number of successors, many of them illegitimate – at least in the author's system of values.

The 'legitimate' successors to Malthus's works include the analysis of the causes, processes, and consequences of the growth of populations and, in political economy, the theory of effective demand, which Keynes revived (1939), affording it great topicality (*The General Theory of Employment, Interest and Money*), as well as the references made to the *Essay on the Principle of Population* by Charles Darwin (1838) and Alfred Russel Wallace (1858).

The illegitimate successors – the neo-Malthusianists – are much more numerous and more visible, having remained in the forefront.

As early as 1822, the Englishman Francis Place, while adopting Malthus's conceptual framework, proposed a much easier and more seductive way of checking population growth than moral restraint: the voluntary limitation of births within marriage (Place, 1822). Knowlton also advocated this approach in the United States (Knowlton, 1833), and the idea met with the approval of scholars such as Carlisle and Stuart Mill.

In 1860 the journalist Charles Bradlaugh set up the Malthusian League in London. The organization went from strength to strength from 1877 onwards, when Bradlaugh and Annie Besant, one of the pioneers of feminism, were prosecuted for obscenity.

Neo-Malthusianism was taken to France by the anarchist Paul Robin, who founded the League for Human Regeneration in 1896, and to Germany by the social democrat Alfred Bernstein, who in 1913 organized two meetings in Berlin, causing quite a stir. However, the neo-Malthusians came up against not only the hostility of the authorities but the distrust of socialist theorists.

At the time, militant feminism was evolving all over Europe, and birth control was just one element of its main objective: the sexual liberation of women. The decisive turn, however, was taken in the US thanks to Margaret Sanger, who in 1916 had founded a birth control clinic in Brooklyn. In 1925 she organized an international neo-Malthusian probirth control conference in New York, and in 1927 the first international congress on population was held. This was the basis of the International Union for the Scientific Study of Populations, which however almost immediately dissociated itself from the neo-Malthusian network.

Managed Care and Psychotherapy in the United States

This article is reproduced from the previous edition, volume 13, pp. 9162–9165, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

The relationship between managed care and psychotherapists is a stormy one, characterized by conflicts about professional autonomy, accountability, and finances. Both managed care professionals and psychotherapists share a commitment to the provision of effective mental health treatment to those in need. But, there is disagreement regarding the methods best to keep high quality behavioral health services affordable and available. This article traces the evolution of managed behavioral care and psychotherapy from the 1970s to the present. Provider criticisms of managed care are addressed. A patient centric approach to managed behavioral healthcare is proposed in which providers and managed care work together to enhance and sustain positive treatment outcomes while eliminating unnecessary costs.

The impact of managed care on the delivery of mental health and substance abuse services has been significant. This article traces the evolution of managed behavioral care and psychotherapy from the 1970s to the present. Provider criticisms of managed care are addressed. A patient-centric approach to managed behavioral health care is proposed in which providers and managed care work as partners to enhance treatment outcomes and keep health care affordable.

The Evolution of Managed Behavioral Health Care

Managed behavioral care is the integration of the financing and delivery of mental health and substance abuse treatment within a system that seeks to manage the accessibility, cost and quality of that care (Marques, 1998: p. 411). The managed health care industry is the result of conflicting economic and political pressures to ensure Americans unlimited access to health care services, regardless of their ability to pay, in a market-based system of health care delivery.

The USA is unique among industrialized nations in its reliance on private employers to voluntarily provide health insurance for their employees (Iglehart, 1999: p. 6). Approximately 65% of Americans receive health insurance through the workplace, 66% of them through a managed care plan (*Facts About Managed Care* 1999). In all other industrialized nations, the government provides health care or requires private employers to provide coverage (Studdert et al., 1999). Fears that double-digit health inflation will cause employers to abandon the provision of health care coverage create a government interest in keeping health care premiums low.

Managing Care in the 1970s

Managed care came into prominence in the 1970s as a result of spiraling health care costs (Mullen, 1995: pp. 2–6). Rapid technological advancement in combination with an aging population created exponential increases in health care spending. Health insurance allowed patients to receive treatment without awareness of the costs, permitting practitioners to 'set their price' without consumer flight. Employers turned to managed care as a solution to escalating insurance premiums and fears of the inefficiency of a government-run health care system.

The 1970s approach to managed care focused on utilization review of hospital care. Utilization review is a process by which a managed care organization (MCO) evaluates whether recommended treatment is medically necessary and, as a result, reimbursable under a health insurance policy. This determination is typically conducted through a comparison of proposed treatment plans with medical necessity guidelines. At first, these guidelines were considered proprietary, creating a guessing game as to the definition of medical necessity. It was not until the early 1990s that Green Spring Health Services became the first managed behavioral health care company to make medical necessity criteria public, training providers on their use.

Managing Behavioral Health Care in the 1980s

As the rapid increase in physical health costs began to slow in the 1980s, mental health costs continued to rise, representing an increasing proportion of the health care dollar (Mihalik and Scherer, 1998: p. 1). Mental health benefits typically covered 28–45 days in a psychiatric hospital. This coverage encouraged overutilization of expensive inpatient services and an overbuilding of psychiatric hospitals. Psychiatric facilities competing to fill empty hospital beds advertised all-expense-paid 'vacations' to lush locations, respite from acting-out adolescents, and retreats for alcoholics with health insurance. One study concluded that 40% of psychiatric hospitalizations were medically unnecessary (Mechanic et al., 1995: pp. 19, 20).

Also in this decade, the medical cost offset of psychotherapy became widely known. Nick Cummings, through his work with Kaiser Permanente, demonstrated that brief, effective therapy could reduce the number of doctor visits of 'high-utilizers' by as much as 65% (Cummings, 1985). These 'worried well' sought treatment despite the absence of an organic cause for

symptoms. Resolution of physical complaints was successfully achieved through psychological treatment of emotional distress. Meta-analysis of other cost-offset studies found 10–33% reductions in hospitalization costs for physical illness following mental health treatment (Mumford et al., 1984: p. 1145). These cost reductions were attributed to the alleviation of the psychological distress associated with a traumatic or chronic illness.

The desire to prevent medically unnecessary psychiatric hospitalization and the potential for medical cost savings resulted in the creation of mental health 'health maintenance organizations' (HMOs). American Biodyne Centers, California Wellness Plan, and Psychology Management Systems were pioneers in the provision of unlimited outpatient mental health treatment designed to reduce inpatient psychiatric costs and overall medical expenses. As with most staff model HMOs, however, rapid access to routine mental health treatment was problematic. To increase appointment availability managed behavioral care incorporated a network model of service delivery similar to those used in medical managed care systems.

Managing Behavioral Health Care in the 1990s

Mental health 'carve-out' companies emerged in the 1990s. These carve-outs, called managed behavioral health organizations (MBHOs), specialize in managing mental health and substance abuse treatment. Health plans pay the MBHO a percentage of the health care premium for all members to manage the mental health utilization of the approximate 5–10% of members who use the benefit. The MBHO performs medical necessity review of the mental health treatment recommended by a network of independently contracted facilities, programs, and mental health practitioners. In 1999, 177 million Americans were contracted to receive mental health services managed by an MBHO (1999).

In the early 1990s the MBHO managed care through a combination of utilization review, discounted fee arrangements, and benefit management. Of mental health treatment dollars 65–80% were paid to inpatient and residential treatment facilities (Hennessy and Green-Hennessy, 1997: pp. 340, 341). Because 80% of mental health expenditures were associated with treatment for 20% of patients, early discharge planning, strategies to improve treatment compliance, and case coordination were managed care interventions for 'high-utilizers' of psychiatric services (Patterson, 1992: pp. 51, 54). The effectiveness of these techniques resulted in savings of 25–40%, at the same time increasing access to treatment for all members.

The late 1990s saw the brief emergence of 'integrated delivery systems.' This approach was based on the premise that practitioners paid to provide all of a member's care would be clinically and financially motivated to treat a patient in the least expensive, but most effective manner possible. Ideally, as the need for treatment intensity diminished, a patient could be 'stepped down' to less restrictive settings within the same facility, maximizing treatment coordination. Instead, costs increased and providers bankrupted. Patients previously treated at one level of care received treatment at all levels of care. Outpatient providers were unable to simultaneously provide and manage care, and still make a profit.

Given the price pressures of the industry, when delivery systems could not integrate, the MBHO industry did. Magellan Health Services acquired four MBHOs covering over 71 million members. FHC purchased Value Health Services and created ValueOptions, an MBHO covering 22 million members. United Healthcare purchased United Behavioral Health covering 20 million lives. This consolidation served as a catalyst for provider political organization and activism.

Criticisms of Managed Care

Most mental health providers oppose managed care. Providers contend that managed care organizations face an inherent conflict between quality and cost control. Well-publicized stories of personal tragedy resulting from bad utilization management decisions have created an environment in which managed care has gone from being the centerpiece of health care reform to its target. Provider criticisms of managed care fall into four categories: (a) increased nonreimbursable administrative time; (b) sacrificing of quality for cost savings; (c) intrusion on professional autonomy; and (d) a lack of MBHO accountability.

Increased Nonreimbursable Administrative Time

Provider dissatisfaction with managed care companies is often reflected in complaints of increased administrative time and decreased income. Many administrative requirements originate in private accreditation bodies' concerns for the quality of care under managed care, but require providers to complete additional paperwork. For example, the National Committee for Quality Assurance (NCQA) requires 'credentialing.' Credentialing begins with the practitioner's completion of a lengthy application and ends following a one- to three-month verification process. The practitioner's education and license are validated. Malpractice history, criminal record, and complaint data banks are reviewed for patterns of misconduct. Credentialing reduces the risk that members will receive treatment from clinicians unqualified to help them or potentially harm them.

Other administrative tasks are associated with ensuring that only medically necessary treatment is reimbursed. Precertification ensures that a member's benefit covers the services to be provided, and the medical necessity of the level and intensity of care proposed. Treatment plan review evaluates patient progress and ongoing necessity for treatment. These reviews also protect the patient from incurring surprise financial liability, and the practitioner from accruing 'bad debt.' Prior to managed care, 15% of provider revenue was written off due to an inability to collect (Luft, 1999: pp. 957, 964).

Sacrificing Quality for Cost Savings

Practitioners presume that a cost containment focus precludes concerns about treatment quality. Managed care payment mechanisms such as subcapitation, case rates, or withholds are criticized for encouraging undertreatment. Yet, most studies conclude that more people access mental health treatment

under HMO capitation arrangements than under fee-for-service arrangements. Although the treatment intensity is less, outcomes appear to be the same (Mechanic et al., 1995: p. 19). There is some suggestion that the seriously mentally ill do not fare as well in the HMO setting, but research design limitations prevent generalization.

Psychologists point to increased utilization of social workers as evidence of managed care's interest in savings over quality. Yet there are no studies to suggest psychologists' results are superior. In a survey conducted by Consumer Reports (Seligman, 1995: p. 965), patients reported equal satisfaction with outcomes whether psychologists, social workers, or psychiatrists provided treatment. Because there are only 70 000 psychologists in the USA, but over 189 000 social workers (Mills, 1997) who provide services at an average of $15 less per session, social work referrals improve treatment access.

The debate over managed care's impact on treatment quality is unlikely to be 'won' because treatment outcomes in mental health are difficult to define and measure (Marques et al., 1994: pp. 22–9). Variations in treatment practices, inconsistent use of diagnostic coding, the cyclical nature of mental health symptom exacerbation, and a lack of professional consensus regarding the definition of a positive mental health outcome make it difficult to determine what works and what doesn't. Patient satisfaction with treatment, although measurable, is not correlated with outcome. Patient self-reports of improvement are inconsistent with providers' perceptions of treatment completion. Despite these limitations, research has consistently determined that mental health treatment works and that managed care has not caused deterioration in these results. While patient and provider satisfaction has diminished, the quality of care has not.

Detracting from Practitioners' Professional Autonomy to Advocate for Patients

Providers resent the imposition on professional autonomy associated with medical necessity review. It is popular to complain of clerical oversight of professional judgment. Although it is possible for unlicensed individuals to authorize or approve recommended treatment according to a professionally developed treatment guideline, the industry standard is that a clinical peer or board-certified psychiatrist renders all nonauthorization decisions. Many states legislate peer review and both NCQA and the Utilization Review Accreditation Commission (URAC) require it.

Fears of 'economic credentialing' pressure clinicians to consider financial factors when recommending treatment, conflicting with professional ethics of patient advocacy. Providers are concerned that only those who treat individuals 'cheaply' will be retained in a managed care network, while providers who favor longer-term treatment, and potentially better outcomes, will be excluded. Yet few providers are removed from managed care networks for patterns of excessive overutilization. The preauthorization requirement often detects and prevents overutilization before it occurs. More common causes for provider termination are noncompliance with credentialing requirements, or provider requests for network removal. Access requirements make narrowing a managed care network solely on utilization unlikely.

Perceived Lack of Accountability

Managed care reform began to appear on state legislative agendas in 1995 and on the congressional agenda in 1996. Providers organized to fight managed care at the state level. Symbolically targeting 'gag clauses,' physicians began talking to the media, raising consumer anxieties about the quality of health care provided by profit-seeking managed care companies. Despite research to the contrary, the public became convinced through anecdote that managed care was destroying US health care.

Public concern about a perceived lack of managed care accountability has resulted in a proliferation of regulation in the last five years. All 50 states have passed some form of managed care legislation. Federal patient rights legislation has been introduced in Congress every year since 1997. NCQA introduced MBHO quality standards in 1996.

Mental health providers, frustrated with managed care's impact on their practices, are diversifying by providing consultation, education, and forensic services. 'Cash only' practices are emerging, with promises of enhanced privacy due to the absence of managed care oversight. For managed behavioral care to continue to evolve in the new millennium, it must repair its relationship with providers. A patient-centric model of managed behavioral care provides a framework in which practitioners and managed care can partner to achieve the shared goal of improving mental health in the USA.

The New Millennium: Patient-Centric Care Management

In the patient-centric model of managing behavioral care, an MBHO hires clinician-care managers who:

improve access to needed services;
match patients to providers who have the skills and experience most likely to result in treatment success;
maximize benefit allocation through medical necessity review of recommended services;
enhance treatment outcomes through intervention with ineffective treatment plans;
sustain treatment gains through aftercare monitoring; and
identify or prevent undetected mental illness.

The patient-centric model of managing care is based on the premise that helping patients overcome an emotional disturbance quickly and keeping them well is less expensive than allowing patients to prematurely abandon treatment and subsequently return to intensive levels of care. Promoting early access to effective providers is consistent with this goal.

In a patient-centric model, individual benefits are managed in the context of the well-being of an insured population. Ensuring that care is only reimbursed when medically necessary, that a patient is treated in an effective and less costly setting, and that patients are referred to practitioners with discounted rates maximizes the value of patients' benefits. Anticipation of benefit exhaustion and transition planning prevents individuals who cannot afford needed care from going without it.

Removal of barriers to mental health treatment is the ultimate value managed care can bring to the therapeutic process. Transportation problems, poorly coordinated care, or identification of contraindicated drug combinations are the clinician care manager's province, allowing the practitioner to focus on treatment interventions. By comparing recommended treatment to practice guidelines based on outcome research, managed care can promote the updating of providers' treatment repertoires. Following treatment, periodic monitoring of a patient's condition or follow-through with an aftercare plan can be effective in sustaining treatment gains. Joint pursuit of these patient-centric objectives permits the consumer to take advantage of treatment and care management resources, while reducing the cost of ineffective or unnecessary care.

Conclusion

In order to continue to reduce the cost of mental health care while maintaining or improving its quality, managed behavioral health care systems must continue to evolve and adapt. A managed care–provider partnership is unlikely to be easily achieved. Although mental health outcome research improved dramatically over the last 20 years of the twentieth century, there is still much professional disagreement about 'what works.' These debates are often the substance of discussion between providers and care managers. At the heart of the animosity, however, is the providers' perceived loss of professional dignity and autonomy. The next evolution in managed care will not occur unless the providers' sense of professionalism is restored. A patient-centric model of managed behavioral care aligns the goals of managed care employees, mental health providers, and purchaser-employers with the best interests of the patient population.

Editor's Note

Two books from the 1990s on managed psychotherapeutic care have recently been issued in new editions: (1) Alperin and Phillips (2013[1996]), and (2) Sauber (2013[1997]). The impact of managed care on the costs of mental health treatment, an issue discussed at length by Weaver and Marques, continue to be researched. For a recent statement, see Crane and Payne (2011). Disparities in access to mental health services under managed care are another current research theme; see Akincigil et al. (2012). Also useful: Olfson and Marcus (2010).

Management Accounting

Alnoor Bhimani, London School of Economics, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The modern-day management-accounting literature originates from late nineteenth-century factory cost-accounting writings. Over the past 20 years, the field has undergone an important transformation as a result of localized as well as global economic and organizational management forces. These forces of change are considered, and important areas of modern management accounting are reviewed. Two management-accounting approaches (target costing and activity accounting) are discussed at greater length. Concluding thoughts are presented on what some scholars and thinkers believe will be the fate of management accounting in the twenty-first century.

Introduction

The Chartered Institute of Management Accountants in the United Kingdom defines management accounting as an integral part of management concerned with identifying, generating, presenting, and interpreting information used for

1. formulating strategy,
2. planning and controlling activities,
3. decision taking,
4. efficient resource usage,
5. performance improvement and value enhancement,
6. corporate governance and internal control,
7. safeguarding tangible and intangible assets.

While the discipline finds its roots in industrial accounting concerns and factory-based cost accounting, it has undergone an important transformation over the past 20 years. The field presently continues to undergo significant changes and remains in a dynamic state of flux. During the 1980s, many organizations in Western countries perceived a need to alter their management practices. A variety of factors were responsible for this. In part, at the international level, competitive manufacturing methods used by major Japanese corporations and by those of newly industrialized countries were seen as superior to those used in the West (Bhimani and Bromwich, 1996). To an extent, this was ascribed to sociocultural characteristics of Japanese workers from factory-floor operators to senior executives. But what was viewed as more significant was the application of flexible manufacturing technologies by the Japanese to produce a greater diversity of high-quality, low-priced products more quickly. Specific modes of work organization, production systems, and motivational incentives were seen to differ radically from those used in the West. These forces of change on management approaches have also been viewed as having had important implications for management accounting practices. The adoption of flexible technologies in manufacturing and service-oriented enterprises, including manufacturing and enterprise resources planning systems, and features of computer-integrated manufacturing, led to conventional accounting methods for cost allocation being questioned. The manufacturing environment had become more automated, more specialized, more flexible, and requiring larger capital investments, whereas methods of costing products continued to operate under the conventional notion that company operations were geared toward repetitive production of homogeneous products relying on labor-based activities. Management-accounting techniques were thus seen to be antagonistic to the realities of the new manufacturing environment. Similar critiques were being made of cost-accounting methods in service industries.

Other calls for change in management accounting were also being voiced. North American academics thought that from the post–First World War period, progress in management accounting had virtually ceased, principally as a result of the growing importance of the external reporting priorities, especially in the area of stock valuation over those of internal organizational accounting. Some critics of traditional management accounting asserted that management accounting had, for over 70 years, been subordinated to the requirements of financial-statement preparation for external parties (Johnson and Kaplan, 1987). Advocates of this school have supported calls for management-accounting reforms based on the argument that the field must once again be allowed to develop in its own right, rather than remain subordinate to financial accounting.

Many commentators made more substantive arguments, focusing on the propriety of accounting practices, given the roles that management accounting is intended to fulfill. The usefulness of complex methods of organizational costing and pricing, in the face of the belief that the price of a product must ultimately meet the expectations of the marketplace rather than those of its producers, has been questioned. Others have given weight to the argument that management accounting has for too long remained isolated and divorced from other enterprise functions. Conventional accounting practices have put into place channels for information flow and routes for data exchange that have rendered some organizations static, inflexible, and excessively structured, especially in the case of firms operating in dynamic and fast-changing markets. Calls have thereby been made for cost-management tools appealing to wider rationales of enterprise management.

Onward with Change

During the 1990s, many organizations pursued a vigorous management change agenda. Until 1994, many organizations shied away from investing in novel enterprise management

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73013-3

philosophies because of the malaise experienced in the worldwide economy. Nevertheless, cost-containment programs were widely implemented. Techniques such as activity-based costing (ABC), throughput accounting, target cost management, life-cycle costing, and the greater use of nonfinancial performance measures were seen as offering the potential of enhancing value creation and aiding cost containment (Bromwich and Bhimani, 1994; Yoshikawa et al., 1993). From 1995, as the economic engine of major Western economies began to generate more steam, organizational searches for wider reaching management technologies grew apace once more. Such pursuits were, however, tempered with a more cautious approach to large-expenditure projects on altering ways of managing. Moreover, accounting techniques for aiding managerial tasks appeared more cognizant of a need to interlink enterprises' various value-creation activities. Thus, management-accounting technologies stressed processes, as opposed to functions, and emphasized linkages between traditional activities, as well as more flexible organizational structures.

Notions of the impact of brand management on cost accountings were highlighted. Attempts to link organizational learning to customer responsivity and financial tracking were made via establishing novel performance-measure control approaches. Traditional conceptions of cost-accounting techniques for scorekeeping purposes were shunned, whereas achieving more balanced scores came to be deemed important (Kaplan and Norton, 1996). Likewise, 'value added' was a significant, although short-lived endeavor among proponents of more comprehensive financial reporting in the 1970s, whereas the pursuit of a trademarked notion of economic value added surfaced (Stern et al., 1995). Certainly, the need to be strategically perceptive in all things management accounting was widely perceived during the mid-1990s. The US-based Institute of Management Accountants changed the name of its flagship magazine *Management Accounting* to *Strategic Finance*. Likewise, the Canadian Society of Management Accountants revamped its intellectual capital whereby its published products came to be grouped as a 'strategic management series' package. No doubt many organizations, in both Europe and North America, consider themselves as engaging and supporting strategic management-accounting activities while not appealing to any single definition of the term (Bhimani and Keshtvarz, 1999; Gulding et al., 2000).

Management Accounting and Digital Technologies

Although computers have shaped business activities for over four decades, it was only during the mid-1990s that a profound second-wave digital revolution took place. Three forces became intertwined at this time:

- the spread of user friendly operating systems and interfaces,
- the rapid diffusion of the Internet and the World Wide Web, and
- the convergence of four formerly distinct industries – computers, software, communications, and media and entertainment.

These three factors led to the creation of a huge worldwide value network with attendant new business models and novel ways for enterprise architectures to form and enable the generation of wealth creation. Concurrently, business intelligence started to crowd out different sources of information.

What consumers and decision makers do with information can insightfully shed light on what drives their purchases or actions. So, traditionally, enterprises have designed information systems to produce formal information that system users deploy based on customer purchases and related economic activities. However, a shift in information design structures is currently taking place. There is now a realization that what information users discard can be equally if not more useful as a source of business intelligence for companies. A customer buying online will often leave a trail of information disclosed prior to making the purchase. This 'data exhaust,' if effectively analyzed, can help organizations determine how and what individuals rationalize and the path they take before they arrive at making a purchase or a decision. Google.com learns from every search process carried out. Amazon.com gathers information from online customer behavior irrespective of whether a purchase is made. eBay monitors buyer and seller activities even where no economic transactions take place. These companies analyze data exhaust in the provision of important financial intelligence, which can shape cost management, pricing decisions, and operational controls.

Drawing business intelligence from information not just on transactions but also on searching behavior, Website surfing, and browsing experience has, for Web-enabled companies, become a basis for competitive engagement. In the future, this will increase in significance. As 'transaction agnostic' information grows, data volume and information management will expand and place important challenges on financial systems.

Globally produced data grows 10-fold every 5 years. The pace is partly reflective of the increase in media, entertainment, and social networking possibilities online. And while much of the information is unstructured, a significant proportion is amenable to structuring in an economically purposeful sense. This growth of information alongside the possibilities presented by data exhaust enables useful analysis and assessment by businesses.

For instance, purchases made via Amazon are often tied to purchases made previously. Probabilities can be established about the likelihood of particular subsequent purchases being made based on data collected about macrolevel buying behavior, nonpurchases, and prior online interactive searches. eBay likewise continuously alters its listings based on prior listing activity, bidding behavior, pricing trends, search terms used, and purchase frequency. Google searches become continuously more relevant because search results are based on what users with prior similar searches eventually stayed with. In this sense, data trails left by surfers enable data mining, which can be deployed to directly impact pricing policy, cost-containment prioritization, and cash and working capital management activities.

While data mining increasingly shapes financial control and management possibilities, traditionally management

accounting systems have been influenced by information collection about products that trigger economic changes.

There is, however, a growing trend toward the collection of information from within products and processes themselves. For instance, real-time data collection is possible without the need for separate information systems, through use of

- pill-shaped microcameras,
- precision agricultural and industrial sensors, and
- radio frequencies identification tags.

Thus, it is possible to achieve continuous information collection on possible product purchase pathways as well as cost changes, dynamic pricing options, and working capital management choices, when products and processes themselves collect and transform information about their own behavior (see Bhimani and Bromwich, 2009; Bhimani, 2012).

This presents novel possibilities for management accounting where it can become a receptor and assessor of information for real-time analysis and decisions.

Strides in Management Accounting

Perhaps it is well to turn to some significant technologies of management accounting that emerged over the past two decades and are now in widespread use within many enterprises globally. Two of these provide the focus presently.

Target Costing

Target costing indicates for each product (and each cost element of that product) the cost reductions (over time) that must be achieved by the firm and its suppliers in order to ensure that the company's strategy is realized throughout the product's life cycle, while maintaining a competitive market price for the product offered. A preliminary step in this process is for the enterprise to come to a view over the whole product life cycle as to the product strategy in terms of the product attributes to be offered relative to competitors, including further options, quality and after sales services, the technology to be used, the desired profit, and market share. A comparison with expected prices in the market over the life cycle of the product determines the price at which the product with the planned characteristics can be offered in the market and be expected to obtain their target profit and market growth.

Target costing in some Japanese companies is seen as a cost-reduction exercise that seeks to achieve cost reduction in the preproduction stages. It seeks to force designers to reduce costs, although how far target prices should seek to include strategy and how far it should be seen predominantly as a continuing cost-reduction device is a firm-specific issue. Such an approach may be supplemented by levying extra costs on nonstandard parts and excessive tooling, as well as penalizing the use of nonstandard parts or new machines. The procedure contains a number of other lessons. One is that prices are determined in the market and reflect competitors' strategies and customers' demands. Target costing also requires that companies collect and use external information that may not be available or, if available, may not ordinarily be assessed by the Finance department. Finally, it illustrates the possibility of incorporating strategy into accounting and performance measurement more generally.

There are a number of ways of setting target costs; these include

1. determining the difference between allowable cost (selling prices – desired profit) and forecast costs determined using current costs,
2. determining the difference between allowable cost (using planning selling price net of the required return on sales) and current costs,
3. applying the desired cost reduction to current costs.

The above description of target costing should be seen as broadly representative of what ought to be done rather than the organizational reality. There is evidence that Japanese firms often fail to make the target cost, at least prior to manufacture, and either adjust the target costs or decide not to continue with the product in its existing form. Target costing practices in Western enterprise likewise evidence a high degree of organizational specificity.

Tools for Target Costing

In Japan, value engineering (VE) is an activity that helps to design products that meet customer needs at the lowest cost while assuring the required standard of quality and reliability. A number of tools are generally used in this activity.

Functional Analysis

The aim is to determine the functions of the product and indicate how far the design of these functions will satisfy the consumer (as shown by market research) and at what cost relative to that part of the target cost pricing by elements allocated to that function. This allows the variance between the target cost-per-function and its current cost to be calculated. It also allows the contribution that a function makes to consumer needs to be ascertained relative to its cost, thereby leading to redesign where two items are not well matched (see Yoshikawa et al., 1993).

Cost Tables

Cost tables are detailed simulated databases of all the costs of producing a product, either for product functions or product components, based on a large variety of assumptions. They allow 'what if' questions to be posed relating to decisions to change any aspect of the product. A cost table will show the variety of cost performances when using different types of materials for a given component. The data in cost tables will be accepted by all members of the organization, and therefore ensure common thinking throughout. There will be a cost table for each part of the product's life cycle.

Value Engineering Collections

These are libraries of case studies of the detailed experience from previous VE activity, the use of which is to improve future target costing and VE. Of course, all the other well-known techniques used in Japan, such as just-in-time methods and quality circles, are utilized, where appropriate, in target-costing exercises.

Enterprise cost structure in Japan is such that, on average, material and components account for some 60% of cost, direct

labor some 14%, and overheads some 24% (Bhimani and Bromwich, 1996), although these percentages can vary substantially across firms and industries. Comparative US figures are material and component costs (53%), direct labor (15%), and overheads (32%). Possibly, high overhead cost incursions could be a signal that for some firms much may be gained from the market-derived discipline that is evident in the target-cost-management process.

Activity Costing

Concerns about overhead allocation have been voiced by many managers and, perhaps more importantly, the need to account in a way that encompasses the activities that cause costs rather than using traditional methods of overhead allocation is recognized by professional accounting bodies.

ABC emerged as a cost-management approach during the late 1980s. It can be defined as an approach to costing that focuses on activities as the fundamental cost objects. It uses the cost of these activities as the basis for assigning costs to other cost objects such as products, services, or customers (Bhimani et al., 2012). During the 1990s, it has increasingly been linked to managerial decisions via time, market, strategy, and quality issues. Examples of ABC calculation can be found in Bhimani (2012).

The published evidence on the payoffs and costs of installing activity-based cost and management information systems is not unequivocal (Bromwich and Bhimani, 1994). Partly, this is because seeking an association between major changes in organizational and management structures and management accounting is a difficult and time-consuming exercise. The practicing management accountant must be satisfied that the benefits likely to accrue from any change will outweigh its costs, although cost-benefit quantification is not a straight forward proposition. Moreover, abstract, theoretical concepts do not tend to succeed in achieving implementation in organizations. To date, there is little evidence that any new accounting method that attempts to facilitate the management decision-making process actually increases the ability to generate greater profits, although providing such evidence is very difficult. Ascribing increased profitability to the implementation of a costing technique, such as ABC, is a difficult exercise. Problems arise in tracing changes in the 'bottom line' to managerial action associated with altered costing information. The inability to isolate the effects of a single change such as the adoption of ABC *ceteris paribus*, and to use another company as a 'control' for comparative purposes, makes any assertion of a profitability link dubious. This is especially so because changes in organizations often come in bundles, after, for example, the appointment of a new managerial team. Perhaps the ultimate test of establishing whether a switch from a traditional cost system to ABC yields increased benefits is a market test that seeks to ascertain whether such a switch becomes a permanent one for a sufficiently large number of companies adopting ABC. Given the relative novelty of this costing approach, however, this test is difficult to apply. Nevertheless, in various surveys of ABC/ABM implementations in UK firms, Innes et al. (2000) report that, in 1995, 13.2% of companies rejected the technique, whereas 15.3% did so in 1999. They conclude:

> All in all, the survey results are not indicative of any further growth in ABC/M but rather suggest at best a leveling off in the extent of its use in our largest companies.

There are many managers who believe that activity-based accounting methods have changed their approach to decision making, indirectly yielding increased profits and, more importantly, a much better understanding of their business (see Cooper and Kaplan, 1998; for case studies). Some problems still exist with overhead allocation where, for instance, the source of the overhead is difficult to trace or is sunk or is common to diverse activities. Arbitrariness and judgment will, therefore, continue to significantly affect overhead cost accounting. There is strong support, however, for the argument that dynamic and changing manufacturing (and nonmanufacturing) environments render redundant, conventional cost-accounting systems that emphasize information priorities other than those emerging as virtually indispensable in today's competitive marketplace. For example, strategic cost analysis, cost-benefit appraisal for long-term projects, life-cycle consideration, quality, and customer satisfaction data are likely to become increasingly meaningful in service and manufacturing environments (Bromwich and Bhimani, 1994).

The Future of Management Accounting

While many other management-accounting approaches have been, and continue to be, developed, aside from activity accounting and target costing, some concerns have been voiced concerning the future fate of management-accounting practices. King (1997), for instance, believes that many management accountants complain that – while their skills may be valued – they are often excluded from management decision making. Accountants are often not seen as starting players on the management team, in part because of their training, which emphasizes precision and accuracy at the expense of relevance. King (1997) suggests that recognizing that there is more judgment – and less precision – in accounting is a first step in what may have to be an extensive program to ensure that accountants will survive into the twenty-first century.

Foster (1996), likewise, believes that change is required in the way in which management accountants operate. Management accounting is in a continual state of adaptation as the knowledge base in the field increases and the business environment changes. According to Foster (1996), management accounting has often been portrayed as focusing too much on internal reporting and on providing information for statutory financial reporting. This portrayal is seen as inadequate. In the future, decisions about which activities to outsource, and how to structure joint ventures with other organizations will be critical management responsibilities. Management will seek financial information

to help plan and monitor ongoing relationships with external partners. Foster (1996) notes that, in the future, one will seek greater recognition of root-cause cost drivers as well as cost drivers arising within and across functions.

According to Flegm (1996), skill with numbers is not enough. Accountants of the future must be experts in the basic disciplines of business, yet also generalists who can manage different disciplines, communicate with clients, and motivate employees. The call for more strategic management accountants, likewise, still rings loud. Kaplan and Norton (1996, 2000) consider that advances since the 1990s have made it possible for management accountants to become part of their organization's value-added team. Management accountants must participate in the formulation and implementation of strategy (Kaplan, 1995), and help translate strategic intent and capabilities into operational and managerial measures.

Management accountants have to move away from being scorekeepers of the past and to become the designers of the organization's critical management information systems. Existing performance measurement systems, including those based on activity accounting, focus on improving existing processes. The balanced scorecard, according to Kaplan (1995), by contrast, focuses on what new processes are needed to achieve breakthrough performance objectives for customers and shareholders.

This call has been voiced in parallel to that for altering management accountants' patterns of behavior (Johnson, 1995). In the past, management accountants focused on how to disclose and report financial accounting numbers, especially cost numbers, so that managers could draw from them more useful information. According to Johnson (1995), instead of focusing on achieving targets, companies' intent on achieving positive long-term results should focus on mastering disciplined and standardized patterns of behavior. Management accountants should work to create channels through which people inquire openly about purpose and method. In this light, Borthick and Roth (1997) note that the management-accounting systems of the future will be a large, real-time database whose data managers anywhere will be able to retrieve, manipulate, and analyze for new problems as they arise. The choice that companies face is whether to be startled by what the future brings or to embrace the future by implementing organization-wide database systems to reap the benefits of better data access.

What seems evident is that each decade brings with it pressures for changing management accounting, as well as different perceptions of the implications of such pressures. The late 1990s heralded in the New Economy where past conceptions of proper organizational management are viewed as being in need of change. A renaissance of liberalization from the past is deemed essential by many old industrial firms facing competition by new giants that did not exist only 5 years before. The Internet economy has made 'modern' management techniques ancestral. Bricks and mortar cardinal principles are being eschewed and replaced by evolving bricks and mortar truths. Life-cycle coasters are now to move at an Internet time pace. Balanced scorecard adopters must tackle new forms of imbalance. Activity accounting systems must begin to appeal to cyber-based cost drivers. Target cost management must now capture the nuances of ephemeral Web markets. While little can be said of where – if anywhere – the future will take management accounting, pundits will continue to dwell on what is essential for its well-being. The finance function must today address novel ways of appealing to information. It must address altered platforms, sources, and architectures relating to information output, channels, structures, and modes of assessment. The sources of change are as multifaceted as are the effects. The global economy is affected by macro- and microlevel changes. Governmental actions are influencing the manner in which enterprises access finance, make use of it, report it, and monitor the risks of their economic activities.

Abstract

Management describes the complex behavior of those responsible for the decisions that determine the allocation of resources, both human and physical, within an organization. The role of general managers is a multifunctional role: decision-maker, strategic leader, human relations expert, custodian of institutionalized values, mediator between business and society, negotiator and power broker. Managers act in a set of institutional contexts and display specific cultural attitudes and styles of action. According to the simplified model of firm behavior under perfect competition, the managerial function is limited to a set of highly rigid decision rules for determining price and output. In real market situations which deviate from the perfectly competitive, market forces are only one of the variables in the complex context where business management takes place. Other key variables concern the corporate organization, the larger group of organizations in which the firm is embedded, state policies and legal systems, and the stategies of both internal and external stakeholders of the firm. The general management function is therefore a very complex one, that includes a set of managerial roles and implies various forms of managerial behavior and style. The focus of this article is on general management, on managerial behavior and managerial roles in organizations. Four main questions are discussed: (a) the rise of managerial capitalism and the separation of ownership and control; (b) what managers really do, i.e., the main features of managerial behavior; (c) the role of managers in business organizations; (d) managerial ideologies and managerial styles.

Management describes the complex behavior of those responsible for the decisions that determine the allocation of resources, both human and physical, within an organization. The role of general managers is a multifunctional role: decision maker, strategic leader, and human relations expert, custodian of institutionalized values, mediator between business and society, negotiator and power broker. It is played in a set of institutional contexts and implies specific cultural attitudes and styles of action. According to the simplified model of firm behavior under perfect competition, the managerial function is limited to a set of highly rigid decision rules for determining price and output. In real market situations which deviate from the perfectly competitive, market forces are only one of the variables in the complex context where business management takes place. Other key variables concern the corporate organization, the larger group of organizations in which the firm is embedded, state policies and legal systems, and the stategies of both internal and external stakeholders of the firm. The general management function is therefore a very complex one, that includes a set of managerial roles and implies various forms of managerial behavior and style.

For specific areas of management see articles on Administration in Organizations; Corporate Finance: Financial Control. The focus of this article is on general management, on managerial behavior and managerial roles in organizations. More specifically, four main questions will be discussed: (a) the rise of managerial capitalism and the separation of ownership and control; (b) what managers really do: the research on managerial behavior; (c) the role of managers in business organizations; (d) managerial ideologies and managerial styles.

The Rise of Managerial Capitalism and the Separation of Ownership and Control

The growing importance of management in the twentieth century is related to the transformation of capitalism and to the emergence of large business organizations, in the form of public companies, that implies the separation of ownership and control. This transformation has been due to a variety of factors, such as technological innovation, generalization of market relations to preindustrial settings, international competition, industrial concentration, and vertical integration. The change has resulted in increasing organizational complexity, multifunctional structures, greater role differentiation, and more decentralized authority.

The transition from family capitalism to managerial capitalism was facilitated by the legal institution of the limited company; it was related to the timing and sequence of the industrialization process in different countries and took place earlier in the UK and the USA than in Continental Europe and Japan. Shareholding has often become very dispersed. Boards of directors have been predominantly composed of fulltime senior executives who nominate new members and take decisions concerning high management appointments and remuneration. Top management has become effectively responsible not only for operating organizations, but also for strategic decisions concerning investment, finance, internal growth and diversification, profit retentions, and acquisitions. Business firms have displayed a capacity for persistent, although irregular, long-term growth in size, as shown by the growing share of the 100 largest corporations in total industrial value-added, which from less than 10 percent in 1900 grew to 30 – 50 percent in various industries in the year 2000.

The growth of the large corporation and the increase in capital concentration, however, are not inconsistent with coexistence of other components of the modern economy, where traditional capitalist modes (markets containing large numbers of small owner-managed businesses), and new forms of productive systems (industrial districts with specific competitive-cooperative patterns among producers in the same industry) not only survive, but effectively compete and grow. In addition, in the last two decades of the twentieth

century, technological developments, such as personal computers, which increase the comparative efficiency of small organizational units, and new institutional developments, such as corporate divestitures and management buyouts, contribute to checking and even reversing concentrating tendencies.

The large corporation and managerial capitalism are neither a general pattern of business organization, nor necessary steps in economic modernization, but they have marked first the economic history of the UK and the USA and later, that of continental Europe and Japan. The 'complete businessperson' – who was at the same time owner, entrepreneur, and manager – slowly gave place to the separation of the property and control functions and to a plurality of specialized roles within the corporation.

Both Marx and Schumpeter saw the separation of the managerial role from the ownership of capital as a sign of the crisis of capitalism. The limitations of both Marx's and Schumpeter's views in this regard is due largely to their belief that the competitive economy of the individual entrepreneur is the only brand of sustainable capitalism. In reality, capitalism has proved compatible with the existence of large, complex firms, and with state intervention and regulation of the economy. What Marx and Schumpeter saw as a crisis factor, other scholars viewed as a stage in capitalist development and a feature of the fundamental process of the growth of the business firm. Influenced by Weber's analysis of the rise of the modern state, Rathenau (1918) argued that with the depersonalization of property and the rise of *'organisierte Kapitalismus*,' the firm followed the same path as, and became similar to, the modern state.

Berle and Means (1932), in their pathbreaking empirical research on two hundred US firms, argued that the separation of ownership and control was an organizational requirement of the modern corporation and an irreversible trend of economic life. Berle and Means conceived the modern corporation as an organized social group based on the interdependence of different economic interests – those of the owners, the employees, the consumers, and the controlling group. This last group has the 'active property' of the firm – as distinct from the 'passive property' of the shareholders – and performs the entrepreneurial function. Managerial power is highly concentrated in the controlling group, as religious power was in the medieval church and political power in the nation state. Conflicts of interest can arise between managers- entrepreneurs and shareholders; the former are mostly interested in reinvesting most of the profit, in order to enhance the firm's competitive power and long-term development, while the latter want short-term economic gains. A more radical view of this conflict was Burnham's (1941), who foresaw a 'managerial revolution.'

Ideas similar to those of Berle and Means's were developed by Coase (1937), Williamson (1975), and Chandler (1962, 1977), who focused on the firm as an alternative allocative mechanism to the price mechanism, and of the 'visible hand' of management as an alternative to the 'invisible hand' of the market. Chandler, in particular, argued that a fundamental reason for the success of the modern corporation was its ability to obtain higher productivity rates by internalizing activities previously performed by separate autonomous business units, by reducing information and transactions costs, and by better coordinating the flow of goods and factors of production. But the advantages of corporate organization could not be fully exploited until a managerial hierarchy was created, made of managers who are rewarded, selected, and promoted on the basis of their professional skills and performances rather than on the basis of their family ties and the money they have invested in the firm. Once formed, this managerial hierarchy becomes the source of continuity, power, and growth in the large firm, and tends to assume a life of its own, independent from the individual turnover at the top.

According to Chandler, the dividing line between entrepreneur and manager is drawn on the basis of the type of decisions they make: the minority of the general executives and owner-entrepreneurs – who are responsible for strategic decisions – are neatly separated from the majority of sectoral managers – who are in charge of specific processes and perform routine activities. Managerial roles in the modern corporation are located along a hierarchy of authority and responsibility. The control of finance, personnel, organization, research, and information is a necessary condition, but is not enough to define a full entrepreneurial role; the role implies also the ability to work out long-term general strategies and the power to allocate the resources necessary to achieve the desired goals (Mathews, 2010).

The thesis of the irreversible diffusion of managerial capitalism has been criticized on various grounds. First, it has been pointed out that managerial control applies only to large firms, whereas, as I remarked earlier, the 'other half' of the contemporary economy is made of small firms, most of which are managed by owner-entrepreneurs. Second, even for large firms, family capitalism is much more resilient than the scholars of managerial control would admit. This seems to be the case not only in Continental Europe and Japan but also in the USA, as Burch (1972) tried to show through the survey he made 40 years later of the same firms that Berle and Means studied.

Third, it has been argued that conflictual views on short- and long-term strategies actually vary according to the conception of corporate control developed by high-level executives. The finance conception of control that was pioneered by US conglomerates in the 1980s provides an instance of short-run gain strategy upheld by top managers (Fligstein, 1990). There are many instances of top managers and owners basically sharing the same interests and values, in spite of the different roles they play, due to the fact that corporate executives, while not often among the largest shareholders, receive incomes that are highly correlated with stock performance, and that a relevant part of their remuneration is the form of stock, dividend income, and capital gains (Lewellen, 1971).

Fourth, scholars like Galbraith (1967) argue that leadership in the large business firm is no longer confined to entrepreneurs, or to top managers; but it is exerted by a technostructure, that is, by all those participants who have specialized knowledge and participate in collective decision making. Technologically advanced and organizationally diversified corporations cannot be governed by single entrepreneurs, or a few top executives; they must be managed by the larger technostructure, or by Mey- naud's (1964) technocrats.

Fifth, the idea of the firm as an alternative allocative mechanism for the price mechanism has been criticized for

neglecting other important mechanisms in the regulation of economic activity, such as clans, cartels, and trusts, employers, and trade associations (Streeck and Schmitter, 1985).

Finally, the very notion of corporate control has been challenged by the studies of interlocking directorates. Mizruchi (1982) and Stockman et al. (1983), among others, argue that public companies, with ownership dispersed among many stockholders, are actually controlled by financial institutions—such as national commercial banks and insurance companies—and through corporate interaction patterns rather than by their top managers. Mintz and Schwartz (1985) found a complex division of labor among financial and nonfinancial institutions. Distinguishing among New York money market commercial banks, regional banks, and national insurance companies, they portray a system where financial institutions simultaneously unite and divide. The densely interlocked groups at the local level – centered around the largest regional banks – are connected to the larger money market banks by a series of bridging links created by the country's largest insurance companies. Control of capital flows enables banks to constrain the actions of nonfinancial corporations and to pursue to some extent centralized decision making (Davis, 2009).

A related view is that of Useem (1984), who views the formation of an intercorporate management network as the driving force in the rise of institutional capitalism, that is, the classwide organization of business. The dispersion of ownership and the superior capacity of managerial hierarchies in large firms were the engine behind the transition from family to managerial capitalism. The creation of transcorporate networks of ownership and directorships – as an extension of individual corporate strategies – generated the change for the emergence of classwide organization. Prerequisites for promotion of top executives are not only decision-making and other abilities within the firm, but also demonstrated leadership outside it; prospects of promotion to top positions are generally enhanced if the aspirant serves effectively on other company boards, plays a relevant role in business associations, and achieves a reputation for having access to higher government posts and for effectively managing the relations with relevant stakeholders of the firm.

Some studies argue that in today's global market, with chief executives operating across national boundaries in transnational corporations and financial networks, managerial capitalism is changing into international capitalism (Vernon, 1971; Makler et al., 1982); an international business class, made up of manager-entrepreneurs with interconnected careers and a common cosmopolitan culture, plays a key role in the world economy (Bottomore and Brym, 1989); and corporate power stems from the ability to control global production networks and financial flows (Held et al., 1999).

What Managers Really Do: The Research on Managerial Behavior

After Fayol's pioneering study (1916), research on managerial behavior grew in the 1950s. Early studies, described as the Work Activity School by Mintzberg (1973), recorded and classified the work activities of managers using simple categories. Carlson (1951) organized a diary analysis of the activities actually performed in four weeks by seven Swedish and two French top managers, supplemented by extensive interviews and by background knowledge. It was a participating research, since it grew out of a longstanding discussion group of Swedish managing directors with Carlson, aimed at improving selection and training procedures for top management posts. The study showed that, with a few exceptions, managers spent most of their time talking and listening (up to more than 90 percent of their time). Most of their activities, apart from formal meetings, were brief, fragmented, and interrupted; they rarely had as much as half an hour a day alone. Managers were exposed to 'administrative pathologies,' such as being overloaded with details or neglecting personal inspection tours.

A second type of empirical research is well exemplified by Mintzberg's (1973) study of the weekly activities of five chief executives in different kinds of organizations. He classifies 10 managerial roles into three main headings: informational, interpersonal, and decisional. Interpersonal roles include figurehead, leader, and liaison, and also negotiator and spokesperson. But the key function is the monitoring and dissemination of information, which makes executive managers the nerve center of the organization and, we can add, provides a major basis for their power. Top managers' foremost professional hazard is the danger of dealing with all issues at a superficial level, because of the variety and brevity of their activities.

A third kind of studies of managerial behavior focuses on differences between managerial jobs. Stewart (1982, 1991) is a good example. She stresses different managerial styles and the constraints, opportunities, and choice models in managerial activity; and she identifies as main criteria of differences the nature and the difficulty of the contacts required in the job, whether the job was a boss-dependent one, and whether the job was an exposed one where the jobholder's mistakes were personally identifiable.

Kotter's (1982) study, based on lengthy interviews and documents of 15 general managers in various companies and their key contacts, introduced agendas and networks as key concepts. He found out that general managers tend to build their agendas—made of loosely connected goals and plans—during the first six months to one year in the job and through the development of a network of contacts. Experienced managers may have the problem of 'tunnel vision,' and therefore require occupational mobility in order to mix with people from various businesses and with different perspectives.

All these studies, and many similar others, contributed to show the complexity of managerial behavior and, at the same time, the difficulty of identifying what is specific about it. Whitley (1989) gives a good summary of what can be considered managerial about managerial activities. He suggests five main features: They are highly interdependent, contextual, and systemic; they are relatively unstandardized; they are changeable and developing; they combine both the maintenance of administrative structures and their changes; they rarely generate visible and separate outputs which can be directly connected to individual inputs.

The limitation of many of these studies is that they underplay the specific organizational contexts where managerial behavior takes place. An exception in this respect is

Hannaway's study (1989), based on almost 30 000 random samples of the work activities of 52 managers, divided into three hierarchical levels, over six weeks. She was interested in how managers behave in a hierarchical social system that is characterized by uncertain tasks, ambiguous outcomes, and biased feedback. Among her most interesting findings are the attempts of managers to protect themselves from blame when things go badly by involving others in any potentially risky decision, and to protect themselves from the ambiguity of managerial work signaling their worth to others. Hannaway's study introduces the research topic of the role of managers in the organization.

The Role of Managers in the Organization

Whereas most psychological studies of management focus on behavior, most sociological studies focus on managerial roles in the organization. A major influence in the study of management in organization was Weber's theory of bureaucratic administration, which fostered a view of managerial authority based on incumbency in a legally defined office and technical competence. Still more influential for the study of management was Barnard's (1938) classical study, which identified in administration, coordination, and control the essential managerial functions. For Barnard, the core of business organizations is the conscious and deliberate cooperation of different individuals for a common goal. Organizations are superior to individuals because of their intrinsic rationality. Accordingly, the function of managers is three-fold: they must take strategic decisions, through the rational evaluation of alternatives; they must assure the consensus and the cooperation of all members of the business organization through shared goals and value premises; and they must achieve a satisfactory mediation between organizational needs and individual expectations. Barnard's view laid the ground for major conceptions of the managerial role, which I will frame in the dominant organizational paradigms.

First, there is the view of the manager as a decision maker and an organization person, as it is derived by the organizational decision-making approach (Simon, 1957; March and Simon, 1958). This paradigm has been widely accepted in management schools; and since management schools are important in shaping managerial roles, it is the most widespread among managers and the most influential in shaping their actual behavior. For Simon, organizations help decision makers both by simplifying decisions and by supporting participants in the decisions they need to make. Organizations encourage decision makers to 'satisfice' rather than maximize – that is, to settle for acceptable as opposed to optimal solutions – to attend to problems sequentially rather than simultaneously, and to utilize existing repertoires of action programs rather than to develop novel responses for each situation. Organizations are necessary because of the cognitive limits of individual decision makers; they support rational decision making by setting integrated subgoals and stable expectations and by subdividing responsibilities among managers and other firm members, providing them with the necessary information, resources, and facilities. According to this view, the manager is mainly the organization person, and managerial behavior is an instance of bounded rationality and is largely influenced by organizational structures. Another version of the manager as organizer is Marris's (1979), who sees the ability to organize the complex functioning of modern large-scale firms as the distinctive feature of management.

The second paradigm is the conception of the manager as the informal, human relations-oriented leader, as developed in the human relations model (Roethlisberger and Dickson, 1939; Mayo, 1945; Likert, 1961), and related ones. It stresses the role of managers in exerting informal leadership, and promoting worker morale, increased effort, and cooperation in the service of organizational goals. From this perspective, good managerial leadership aims primarily at influencing the behavior of individual participants, and is conceived as democratic rather than authoritarian, employee-centered rather than production-centered, concerned with interpersonal relations and informal status hierarchies rather than with bureaucratic rules and formal authority. The human relations perspective stimulated relevant research and business policies aimed at increasing productivity through changes in work organization (job enlargement) and/or workers' participation in decision making. But, it was criticized both on ideological grounds – for de-emphasizing the actual conflict of interests between workers and management – and on empirical grounds, since several decades of research have demonstrated no clear relation between worker satisfacton and productivity, between leadership style and worker productivity, and between participation in decision making and worker satisfaction (Strauss, 1963; Hollander and Julian, 1969).

The third conception, best represented by Selznick (1957), is that of the manager as custodian of institutionalized values and mediator between organization and society. It is couched in the institutional paradigm and seeks to explain changes in the operative goals of the organization in the face of environmental constraints. Intellectually indebted to Michels and Merton, Selznick proposed to study the natural history of organizations by focusing on critical decisions that foster structural change. He discussed how they develop distinctive structures, capacities, and liabilities, through which they become institutionalized, that is, 'infused with value beyond the technical requirements of the task at hand' (Selznick, 1957, p. 17). For him, informal structures can never succeed in conquering the nonrational dimensions of organizational behavior, because organizations are concrete structures that must adapt to pressures of their institutional environment, and because they are made of individuals who participate as 'wholes' in the organization and do not act merely in terms of their formal roles within the system. Accordingly, managers issue their directives, although they may be neither understood nor followed by their subordinates. The managerial role is, therefore, defined not in terms of managers' authority, but of their relation to institutionalized values. Since organizations reflect and protect societal values, managers act as catalysts in this process (Scott and Davis, 2007).

The fourth view is that of the manager as a negotiator in a conflict-ridden context and as a power holder, or as I prefer to define it, a power broker. It can be drawn from both Cyert's and March's (1963) behavioral approach, from the students of organizations as negotiated orders, and as political arenas, like Crozier and Friedberg (1977) and Daudi (1989). In this

view, the plurality of goals, and the diversity of interests and outlooks among participants, make conflict not a symptom of organizational malfunctioning, but a normal feature of organizational life. According to Cyert and March, managers can adopt various mechanisms for conflict resolution, such as the budget – which stabilizes previous negotiations and expectations – standard procedures and operational rules, informal relations and traditional practices. Real strategies within the firm do not rationally maximize corporate ends but result from compromises within the dominant coalition and between the coalition and other collective actors.

The complex relation between corporate management and control and the insitutional context is also at the core of Fligstein's (1990) study on *The Transformation of Corporate Control*. Rooted in the paradigm which sees organizations as continuously transforming open systems, Fliegstein argues that changes in corporate control take place in three relevant institutional contexts. First of all, the firm itself is the institutional context where the internal strategy and structure of existing firms reflect organized power and interests, and managers' ideas about appropriate corporate behavior in the light of existing conventional wisdom. Second, organizations are embedded in larger groups of organizations which are called organizational fields, that may be defined in terms of product line, industry, or firm size (suppliers, distributors, financial agencies and, most often, competitors). The organizations that surround the firm provide constant information as to what is occurring in the firm's product markets – which are filtered, interpreted, and greatly affect what actions are possible. Third, the state sets the rules that define what organizations can do and what the limits of legal behavior are. Legislatures and courts define the rights and privileges and set the boundaries of appropriate corporate behavior. Antitrust laws, for instance, define the limits of competitive behavior. Managers' courses of action are not so much constructed in terms of self- interest (whether it be that of the shareholder or the managers themselves), but rather in terms of the legal framework and the self-conscious version of the world that make old and new courses of action possible and desirable. Fligstein reminds us that the worlds of top managers have always been highly structured and their actions shaped by social and political contexts.

With a more radical departure from previous approaches, the perspective of the organization as a negotiated order brings the actor back at the center of organizational analysis, and focuses on concepts like power, strategic game, dominant coalition, and negotiated order. Crozier and Friedberg (1977) do not see organizations as the product of individuals and groups to established roles and procedures, but rather as the result of games in which the freedom of the various actors playing is limited by the formal and informal rules of the organization. Their vision, however, does not amount to diluting organizational action into a sum of individual actions, because the outcomes of interactive strategic games are real organizational properties, and because all participants need a certain amount of cooperation from others and share with them a common interest in organizational survival. By virtue of each actor's constrained freedom, they have power over the other players, since each actor is a source of uncertainty for them and for the organization as a whole. According to this conception, managers can be seen as special players who have greater control over uncertainty areas and are consequently more able to mobilize appropriate resources, like specialized competence, control of information, manipulation of norms, and control of the relations between the organization and the relevant environments.

More explicitly focused on power is Bacharach and Lawler's (1980) model, which introduces the conception of managers as power holders. Indebted to Michel's classical work on political parties as organizational oligarchies, this approach sees managers as power holders, both in the informal structure of influence and in the formal structure of authority. It analyzes the power games, coalitions, alliances, and conflicts organization leaders play both within the dominant coalition and with other antagonistic groups, and the relations between these leaders and their followers.

Related to the view of the manager as a power holder is the study of politics in management. The classical study, Dalton's (1959) *Men who Manage*, analyzes how a group of middle managers distorted the information that they gave to head office to forward their own political goals. Managers have more opportunities than other employees to gain resources and to form alliances in order to forward their career. In the study of politics in management, the image of the manager is often reversed. Managers are not described as acting primarily in the interest of the organization, but in their own interest. From being the heroes of the successful corporation through efficient administration, sound financial control, and profit-maximizing strategies, they become the rulers of bloated bureaucracies that do not produce sufficiently high returns on investment to stockholders, and concentrate on their personal aggrandizement.

Managerial Ideologies and Managerial Styles

Two major pioneering studies of managerial ideologies were published in the same year: that by Bendix (1956) and that by Sutton et al. (1956). The former is a comparative-historical study of managerial ideologies, i.e., of all those ideas which aim at justifying and explaining managerial power and authority within the firm and, indirectly, the social status of the business class. Managerial ideologies are internalized by entrepreneurs and top managers and are exposed on their behalf. The changes in ideologies of management during the nineteenth and twentieth centuries in Anglo-American and Russian civilizations are both similar and divergent; they are similar insofar as they share the increased managerial concern with the attitudes of workers, which presumably account for their differential productivity; they diverge because in the Anglo-American historical environments the authority relations between employees and workers remained to a large extent autonomous realms of group relations, whereas in pre- and postrevolutionary Russia, the conduct of both employers and workers was regulated by the superordinate authority of the state.

Whereas Bendix's study is a comparative historical analysis of social theories and ideas worked out by thinkers who interpret the ideological needs of business elites to legitimize managerial power, Sutton et al. study the explicit public statements of US managers and entrepreneurs. They conceive ideology not as a specific device for legitimizing power in the

business organization, but as a multifunctional mechanism capable of alleviating the strains to which business- people are inevitably subject. Three major types of strains are identified: (a) strains stemming from criticism of the dominant position of business in society, that can undermine the businessperson's belief that corporate values are consistent with US culture; (b) strains originating from the contradictory demands put to the businessperson by the different interlocutors (stakeholders in today's language), i.e., stockholders, employees, competitors, consumers, colleagues; and (c) the strains deriving from the conflicting demands of other social roles that entrepreneurs and managers play outside the firm – in family, community, and various informal groups.

Within the limits of their own cultural traditions, businesspeople adhere to their particular kind of creed to resolve emotional conflicts, overcome the doubts, and alleviate the anxieties engendered by the actions that their roles as entrepreneurs and managers compel them to take. For individuals in business, the function of the ideology is to help them maintain the psychological ability to meet the demands of their job. For instance, the conflict of values between profit and ethics can be eased in two opposite ways: either by affirming that devotion to profit is not inconsistent with social welfare but is, rather, a prerequisite of economic efficiency; or by denying that private profit is, or ought to be, the principal orientation of the business enterprise. Given the importance of business, it follows that ideology has functional importance also for those on whom the actions of business people impinge and for the whole society.

Most research on managerial behavior and roles has been limited to one country. Studies on cultural differences in managerial styles have been more comparative, like Bendix's. Relevant cultural studies of management focus on managerial styles and distinctive national traditions. They usually adopt a comparative perspective and compare Western Europe and North America with Japan, and, until the fall of the USSR, Western and Soviet managerial styles and cultures (Boddewyn, 1971). Another group of research does not compare countries and socioeconomic systems, but rather different types of enterprise, along the private – public and the national – multinational dimensions.

The comparison with Japan is framed in the notion of the diversity of capitalisms that compares the US model of 'market-driven capitalism' with the European model of 'market social economy' and with the Japanese model of 'patronage capitalism.' The Anglo-Saxon model seems more competitive and more effective in job creation, whereas the Continental European one appears more effective in combining competitivenes and social cohesion. The Japanese experience is of interest for two main reasons: the successful competitive performance of Japanese firms in the world market, and recent technological changes that have made the Taylorist – Fordist types of work organization obsolete.

Drawing on the Japanese corporations' experience, authors like Dore (1973) and Ouchi (1981) have argued that managerial styles based on hierarchical relations have clear limits to their effectiveness. Overtly bureaucratized organizations, both of the Weberian type and on the Taylorist – Fordist model, lead to internal failures of functioning because of their rigid and participation-stifling nature. Clan forms of authority and the related styles of leadership, like those existing in the work groups and quality circles of Japanese firms, are more efficient, since they rely on the close ties and personal connections among the members of the group. Besides, this style of management develops noneconomic incentives, such as those based on collective identity and a sense of collective goals, which contribute to raise workers' morale and motivation (Markus et al., 2006).

Managerial career patterns are consistent with this culture, in the sense that institutional loyalty is a core value for Japanese managers, whereas for US and European ones a professional self-definition seems to prevail, in the sense that moving from one firm to another in order to improve one's career is considered fully legitimate. How far Japanese managerial styles depend on the cultural environment of Japan – which favors an especially compliant, deferential, and hardworking labor force – can be tested by studying the experience of Japanese-run firms recently set up in Western countries. Although the number of studies carried out so far is small, it does seem that Japanese management practices can operate with some success in a more individualistic labor force. Studies of Japanese-run plants in the USA, UK, and other Western European countries (White and Trevor, 1983) indicate that bottom-up decision making does work outside Japanese society. Workers seem to respond positively to the greater level of involvement these plants provide, as compared to that of the Western style of management to which they were previously exposed. In recent years, however, the complex impact of globalization and the slower growth of the Japanese economy have put strains on the distinctive Japanese model and redirected it, to some extent, toward the market-led model of capitalism and US styles of management.

Another important instance of of cross-cultural influence in managerial styles has been the imitation, and to some extent the imposition, of US managerial values and practices in France and other Western European countries as a consequence of the USA's victory in World War II (Boltanski, 1990).

The comparison of managerial styles and cultures in private and state-controlled enterprises has been another relevant, although declining, area of study. State-controlled firms differ to some extent from private ones because of their patterns of recruitment and socializing agencies and because of the distinctive features of their business environment. Public firms, managers tend to come more often than their private firms colleagues from either government bureaucracy, as in the French case, or politics and the liberal professions, as in the Italian case. They often have a distinct political-ideological imprinting, as did the managers of postwar British nationalized industries (who had Labour Party affiliations) or the managers of postwar Italy's state-controlled firms (who had been educated at the Catholic University of Milan and had political experience in the Christian Democratic Party). They often showed different attitudes to labor relations and in corporate strategies because their dependence on state policies may have caused diffusion of targets, subordination of corporate goals to broader 'social' ends, and interferences by specific party factions and interest groups.

While some authors (Rees, 1984) point out that they can act according to more flexible cost-opportunity criteria of management efficiency, others (Martinelli, 1981) argue that they risk experiencing a threefold subordination: to private

capital, which uses state controlled firms to get rid of unprofitable businesses and to socialize losses; to political parties, who use them for quelling social tensions and granting benefits to specific interest groups; and to unions, who find in them a weaker counterpart than private companies, and a place where they can win 'easy' victories at the state budget's expense. However, these differences should not be exaggerated, especially for managers of public firms that compete with private ones in the same market environment.

A growing field is the study on executives' managerial cultures and styles in the extensive literature on multinational corporations (Weinshall, 1977) and on globalization (Held et al., 1999). The prevailing view is that managers of multinational corporations do not differ significantly from national firms' managers, except for a greater emphasis on cosmopolitan values and styles of life, a greater sensibility for the scope of their decisions, and a greater alertness to the different societal environments in which they work. An interesting area in the analysis of multinational corporations' leadership styles is industrial relations, where a unified employers' strategy confronts a number of fragmented and diversified trade-union strategies (Makler et al., 1982; Hollingsworth and Boyer, 1997).

As for the impact of modern globalization on managerial cultures and styles, contradictory tendencies are at work. On the one hand, distinct national and corporate-specific managerial styles persist, as do distinct institutional arrangements (different functions played by states although declining in their sovereign power, distinct trade-union strategies and organizations, specific organizational devices for increasing efficiency and workers' morale, etc.). On the other, the increasingly interconnected market economy fosters the diffusion of a common managerial culture and of cosmopolitan attitudes and styles among managers. It is still an open question to what extent this cosmopolitan culture is the diffusion of a single US-inspired model or the result of a hybridization of management styles and cultures. This seems the most promising line of future research in managerial roles, cultures, and behavior (Guillen and García-Canal, 2009).

Managerial and Organizational Cognition

Gerard P Hodgkinson, Warwick Business School, University of Warwick, Coventry, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Incorporating the insights of the full range of the behavioral and social sciences, managerial and organizational cognition (MOC) is an interdisciplinary endeavor that seeks to advance fundamental and applied knowledge of how individuals and social units in human organizations acquire, store, recall, interpret, and act upon information. Originating during World War II, the study of cognition in the workplace has progressed from being a largely monodisciplinary application of experimental cognitive psychology, with a view to enhance practices targeted at helping individuals to overcome fundamental information processing limitations, to a much richer conception of people and their jobs. Situated at the nexus of the cognitive and organizational sciences, MOC is continuously evolving new theories, research, and tools to better explain and predict behavior in and around the workplace, thus improving the effectiveness and well-being of individuals and intra- and interorganizational collectives.

Introduction

Managerial and organizational cognition (MOC) is an interdisciplinary endeavor that seeks to advance fundamental and applied knowledge of how individuals and social units in human organizations acquire, store, recall, interpret, and act upon information. Its scope is as broad as the entire field of management and organization studies, offering cognitive perspectives on topics and subfields as varied as entrepreneurship (Baron, 2004; Grégoire et al., 2011; Shepherd and Krueger, 2002), industrial–organizational psychology (Avolio et al., 2009; Hennessey and Amabile, 2010; Hodgkinson and Healey, 2008; Lord et al., 2010), organization theory and design (e.g., Huber, 1991, 2004), and strategic management (Powell et al., 2011; Hodgkinson and Sparrow, 2002; Huff, 1990; Porac et al., 1989). Although its main foundations were initially psychological in nature, MOC now also incorporates the insights of sociology, philosophy, behavioral economics, and social neuroscience, among other disciplines.

Historically, research on cognition in the workplace has fallen under two major traditions, namely, the human factors tradition and the organizational tradition (Hodgkinson and Healey, 2008). The human factors tradition began during World War II, with the prime intention of enhancing military efficiency and effectiveness. Advancing the human information processing approach to the analysis of skilled behavior, psychologists pursued a program of basic research, which inter alia informed the design of control and display systems pertaining to aircraft, warships, and related military equipment, the scheduling of work, and the design of wider task environments. During this foundational period, skilled performance was modeled as a series of computer-like input–throughput–output processes (e.g., sensory mechanisms, memory functions, and decision outputs), which, when operating in concert, generally culminated in faster performance with less error (see, e.g., Broadbent, 1958; Welford, 1976; Wickens and Carswell, 2006).

Post–World War II, as industrial processes became increasingly more complex, the experimental approach of cognitive psychology that had underpinned the human factors tradition of the war effort continued, as researchers turned to investigate directly the nature and impact of human operators' mental representations of their tasks and the wider systems in which they were embedded (see, e.g., Edwards and Lees, 1974). More recently, following the rise of computer-based work systems, research and theory development within this tradition has centered primarily, although by no means exclusively, on human–computer interaction (see, e.g., Card et al.'s, 1983, seminal volume). From basic desktop machines to modern-day flight decks, the impact of contemporary work in the human factors tradition has been considerable.

Soon after World War II, the late Nobel Laureate Herbert Simon's seminal volumes, *Administrative Behavior* (Simon, 1947) and *Organizations* (March and Simon, 1958), were published together with Cyert and March's (1963) classic work, *A Behavioral Theory of the Firm*. Collectively, these books laid the foundations of the second major tradition in the analysis of cognition in the workplace, namely, the organizational tradition. Work in this tradition conceived organizations as constellations of boundedly rational actors, each beset with fundamental information processing limitations of attention and perception, and which all too frequently embarked upon suboptimal courses of action. This body of work thus established the 'computational perspective' within the organizational tradition (Lant and Shapira, 2001), exemplified by the heuristics and biases program of work pioneered by the late Amos Tversky and Nobel Laureate Daniel Kahneman (see, e.g., Tversky and Kahneman, 1974).

An impressive volume of evidence has been amassed consistent with the idea that in order to render the world manageable, organizational decision makers employ a variety of 'rules of thumb,' known as 'heuristics.' Heuristic processing strategies enable the decision maker to cut through the welter of information bombarding them, by imposing a number of simplifying assumptions on the data. Simon (1957) identified one such heuristic, known as 'satisficing.' According to Simon, faced with a number of choice alternatives, decision makers select the first alternative that meets their minimum requirements, rather than choosing the best from all the alternatives on offer. Satisficing is much simpler in terms of its cognitive operations, thus placing fewer demands on scarce mental

resources. Over several decades, researchers have identified other heuristics that, in common with satisficing, involve less mental effort and there is strong evidence suggesting that heuristic modes of reasoning underpin human judgment processes in the workplace (for details, see Hodgkinson and Sparrow, 2002). Although the use of heuristics reduces the information processing requirements on the decision maker, there are also risks involved, in that their deployment may lead to suboptimal or 'biased' outcomes. In the case of satisficing, for example, once an 'acceptable' option is found, the search for, and evaluation of, additional potentially viable alternatives ceases. Consequently, 'better' options that have yet to be considered will be ignored. The practical implications arising from this work are that, decision makers should be encouraged to expend greater cognitive effort and reason more systematically with a view of debiasing their judgments. However, precisely how this might be accomplished remains the subject of considerable controversy, with only limited high-quality scientific evidence supporting some of the more popular practices in vogue.

Computation versus Interpretation

The work of Karl Weick and colleagues (e.g., Weick, 1979, 1995; Sutcliffe and Weick, 2008) has challenged a number of the core ontological assumptions on which the computational perspective within the organizational tradition is predicated, in particular the assumption that task and wider institutional environments are objective entities that can only be partially comprehended, due to limited processing capacity. Advancing an alternative account, predicated on an interpretivist philosophy, Weick and colleagues maintain that decision makers literally create their own constraints through active, constructive processes of 'enactment' and 'sensemaking,' variously rearranging, isolating, and demolishing seemingly objective features of their surroundings, in turn giving rise to intersubjective differences in perceptions of reality.

In the final analysis, as argued by Lant and Shapira (2001), the processes of bounded rationality and sensemaking and enactment, highlighted variously by scholars whose work has been informed respectively by the computational and interpretive perspectives, ultimately coexist in a dynamic interplay. The former, exemplified by the work on mental representations and behavioral decision research, draws attention to the fundamental information processing limitations of organizational decision makers and the strategies they employ in the *downstream* choice or calculation processes at the heart of decision making and problem solving, in an effort to overcome those limitations, whereas the latter, exemplified by the work of Weick and colleagues, emphasizes the *upstream* processes adopted by individuals and groups to extract patterns of meaning from ambiguous environmental cues in the social construction of organizational realities.

Upper Echelons Theory

Another classic development worthy of brief mention at this juncture is the upper echelons theory of strategic decision making (Hambrick and Mason, 1984). Drawing on many of the foregoing concepts, this theory maintains that senior executives forming the organization's dominant coalition make decisions under bounded rationality, based on their interpretations of the organizational circumstances that they are involved in, and that their interpretations of those circumstances are necessarily partial, informed by the 'administrative givens' they bring to bear on the situation at hand. These givens originate from executives' education, prior work experience, personal values, and a host of related individual differences that direct their attention selectively and shape their perceptions. Unfortunately, however, the highly sensitive nature of the issues and problems confronting executive teams, to say nothing of the time pressure under which they function, renders access for research purposes highly problematic. Hambrick and Mason (1984) thus advocated methods that obviate the need to employ direct methods of cognitive assessment, using executives' background characteristics (e.g., education and functional specialization) as proxies for cognitive variables (i.e., values and beliefs) in the prediction of organizational outcomes (e.g., innovation and firm performance). A detailed consideration of all the available evidence for and against the upper echelons perspective lies beyond the scope of an article of this nature. Here, it is sufficient to note that from the early 1990s onward, the upper echelon approach has been the subject of growing theoretical and empirical scrutiny, amid numerous contradictory and inconsistent findings. Responding to these challenges, more recent work has incorporated direct methods of cognitive assessment in an attempt to isolate the determinants and consequences of executive perceptions and beliefs (see, e.g., Chattopadhyay et al., 1999; Markoczy, 2001).

Current and Emerging Directions in Theory and Research

Foundational Concepts under Scrutiny

Each of the foregoing developments, located variously along the computation – interpretation continuum, pervades the main substantive domains of inquiry that constitute MOC. However, a number of foundational concepts at the heart of the human factors and organizational traditions are giving way to alternative conceptions. For instance, the 'taken-for-granted' notion that cognition resides exclusively in people's heads (as implied by stage-based human information processing models of decision making and skilled performance) is increasingly less tenable. Thus, for example, researchers pioneering the 'cognitive engineering' approach in the human factors tradition, emphasizing the importance of understanding the myriad of interactions that occur between task and environmental constraints on one hand and operators' knowledge structures on the other hand (e.g., Zhang and Norman, 1994), are beginning to examine the role of complex workplace technology as both a shaper and repository of knowledge (see also Hutchins, 1995), a trend paralleled in the organizational tradition (cf Walsh and Ungson, 1991).

Although the basic mental models concept, coined initially by Craik (1943), continues to play a central role in the more recent work of both traditions, it, too, has been problematized, with usage ranging from a manner akin to Johnson-Laird's

(1983) initial conception of mental models as temporary dynamic models in working memory, to the notion of enduring knowledge structures in long-term memory, akin to Bartlett's (1932) notion of schema. Not surprisingly, this basic lack of agreement pertaining to the definition and usage of the notion of mental models at the individual level has similarly hampered progress at the team, organizational, and interorganizational levels of analysis, resulting in a proliferation of constructs and techniques for operationalizing the various notions in play (for critical overviews of these developments, see Hodgkinson and Healey, 2008; Hodgkinson and Sparrow, 2002; Walsh, 1995).

Rethinking Bounded Rationality and the Role of Intuition

Work extending the basic ideas of Kahneman and Tversky – the epitome of the computational perspective – has also come under increasingly critical scrutiny on philosophical, theoretical, and methodological grounds. Predicated upon a fundamentally different conception of Simon's bounded rationality notion from that construed by traditional heuristics and biases researchers, known as ecological rationality, Gigerenzer and colleagues (e.g., Gigerenzer, 1991; Gigerenzer and Goldstein, 1996) have identified a new class of heuristics, known as 'fast and frugal heuristics,' which they maintain are adaptively better matched to the informational structure and demands of decision makers' everyday environments than those studied conventionally by decision researchers, based on the work of Kahneman and Tversky. Arguing that many of the experimental studies demonstrating the irrationality of human judgment are based on tasks involving probabilistic reasoning and other forms of abstract judgment that are far removed from the real-world environments to which humankind has readily adapted over many years, Gigerenzer and colleagues' fast and frugal heuristics make minimal computational demands on the decision maker, do not involve probabilities and utilities, and are deployed in situations that require individuals to draw inferences with limited time and knowledge. According to Gigerenzer and his colleagues, fast and frugal heuristics complement *satisficing heuristics*, i.e., heuristics for searching through available alternatives. The latter are deployed in choice situations where the decision maker does not know much about the possibilities ahead of time. However, as observed by Hodgkinson and Healey (2008), very few studies have investigated the deployment of fast and frugal heuristics in naturalistic settings and the limited work to date has yielded mixed findings regarding the extent to which decision makers actually rely on heuristics falling within this class and with what effect.

A second group of researchers, falling under the umbrella of naturalistic decision making (NDM), similarly rejects the notion of equivalency between the sparse confines of the laboratory and the infinitely richer settings in which organizational decision makers conduct their everyday affairs. Originating in studies of domain experts making complex, high stakes, and ill-structured decisions under time pressure, often in dangerous situations, NDM has gathered momentum over the past decade, both in organizational (Lipshitz et al., 2006) and human factors (e.g., Lipshitz and Cohen, 2005) applications. In theoretical terms, Klein's (1993) recognition-primed decision making (RPD) model, with its emphasis on the crucial role of pattern recognition in obviating the need for extensive deliberation of multiple alternatives, epitomizes the NDM approach. In marked opposition to the prescriptions of Kahneman and Tversky's work, which views intuition as a potential source of cognitive bias, the RPD model highlights intuition as an important foundation of skilled performance in many everyday situations. Interestingly, Kahneman and Klein (2009, 2010) have recently collaborated on a series of articles in which they have outlined a series of conditions that they agree, when present, warrant the use of intuition to enable effective decision making.

Emotionalizing MOC

In the wake of advances in social cognitive neuroscience (e.g., Lieberman, 2007) and neuroeconomics (e.g., Loewenstein et al., 2008), MOC researchers are turning to study the role of affect (i.e., feelings and emotions) in organizational decision processes and strategic adaptation. To the extent that behavioral plausibility is a desirable criterion for management and organization theory (Gavetti et al., 2007), social neuroscience has an important role to play in defining what is behaviorally plausible (Healey and Hodgkinson, 2014). Computational models of human thinking and action based purely on 'cold' cognition still predominate in management and organization theory (Hodgkinson and Healey, 2008). However, continuing to build MOC theory on computational models that are themselves a product of the experimental psychology of the mid-twentieth century is problematic because, contemporary psychological science suggests that many aspects of behavior once thought as the preserve of cold cognition rely heavily on affective mechanisms. The turn in MOC to embrace hot cognition – informed by neuroscientific studies of the mechanisms recruited by behavioral phenomena such as attention, decision, and sensemaking – thus demands a rethink of the field's fundamental assumptions concerning human cognition (Hodgkinson and Healey, 2011).

Refining Methodological Assumptions and Techniques

Going forward, techniques that have been developed over many years as a basis for studying individual and collective 'revealed representations' of explicit knowledge in and around the workplace (see, e.g., Huff, 1990; Fiol and Huff, 1992; Shadbolt and Milton, 1999; Sparrow, 1998) must now be adapted to meet these new challenges. In addition, new methods are required to study implicit representations of knowledge. To this end, innovative procedures such as the implicit association test for the assessment of implicit attitudes (Greenwald et al., 1998) and the use of subconscious priming techniques (see Shantz and Latham, 2009) to investigate subconscious goals (Latham et al., 2010) are on the ascendency; although, several nontrivial theoretical, methodological, and ethical challenges have yet to be resolved (cf Jost et al., 2009; Tetlock and Mitchell, 2009). Arguably, one of the biggest methodological challenges that has yet to be resolved is the question of how to achieve

unified accounts of cognitive–affective–behavioral functioning that interconnect individual microprocesses (e.g., basic judgments and choices) and collective behavior (e.g., group and team functioning, organizational innovation, and interorganizational dynamics), while avoiding the problem of reductionism and related philosophical pitfalls (cf Healey and Hodgkinson, 2014; Powell et al., 2011).

Concluding Remarks

As noted at the outset, the scope of MOC is as broad as the entire field of management and organizational studies. Hence, in this short article, it has only been possible to offer a thumbnail sketch of selected concepts and theoretical approaches. Important topics that are not surveyed in this brief article include identity (e.g., Ashforth and Mael, 1989; Haslam, 2004), attribution (Martinko et al., 2006), and learning (e.g., Huber, 1991; Wood and Bandura, 1989). Each of these major bodies of work, together with those discussed in greater detail in the previous sections, contributes to the vibrancy of this diverse and exciting eclectic field.

Mania

Neel Halder, Alpha Hospitals, Bury, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Bipolar disorder, previously known as manic depression, is a chronic episodic mental illness associated with behavioral disturbances. It is characterized by episodes of mania (or hypomania) and depression, and either one can occur first. A diagnosis of bipolar requires at least one depressive episode and at least one manic or hypomanic episode. This article explores the history, diagnosis, epidemiology, course and prognosis, etiology, and management of bipolar disorder. The management of the depressive phase is similar to unipolar depression, and is covered in the article Depression.

Introduction

> When I came out of the hospital … I fancied that I hadn't had anything, only afterwards did I have the feeling that I'd been ill. What can you say, I have moments when I'm twisted by enthusiasm or madness or prophecy like a Greek oracle on her tripod.
>
> Vincent van Gogh, 3 February 1889, in a letter addressed to his brother Theo

Mania is a serious mental disorder characterized typically by elevated mood, a quickening of speech and thoughts, a feeling of having more energy, and need for less sleep, grandiosity, occasionally heightened sexuality and irritability. *The Oxford Dictionary* (2010) describes mania as a "mental illness marked by periods of great excitement or euphoria, delusions, and overactivity." The word mania comes from the Greek word literally meaning 'madness.' Depression has been covered in the article 'Depression'.

History of Bipolar

In the first century BC, the Greek physicians suggested a connection between melancholia and mania. Just as they thought melancholia resulted from an excess of 'black bile,' mania was thought to result as an excess of 'yellow bile.' In the nineteenth century French doctors started thinking of mania and depression as being on the same continuum: 'la folie double forme' (Baillarger, 1854), and 'folie circularie,' a circular form of mania and depression (Falret, 1854). Although Falret (1854) had described mild forms of mania, Mendel (1881) was the first person to define 'hypomania' as a "form of mania which typically shows itself only in the mild stages, abortively, so to speak." Kahlbaum (1882) described cyclothymia as milder changes in mood shifts but not enough to become depression or mania. It was around this time when van Gogh produced his paintings, and future historians would comment on how they could tell when he was in his more elated and more depressed stages of his illness from his paintings alone (see **Figure 1**). This is made easier due to the large number of letters written by van Gogh, all dated and many detailing his state of mind and health, and therefore making it possible to match the paintings to the letters. The painting shown was completed in what was described as the most productive period of his painting career, and the use of the vivid colors and the content of blossoming trees are in sharp contrast with the darker colors shown in the article 'Depression'. Kraepelin (1921) then made the leap and separated mood disorders from others such as schizophrenia, introducing the term 'manic depressive.' Leonhard in 1957 used the word 'bipolar' to distinguish between people who experienced mania and depression, and 'unipolar' for those with depression only (Leonhard, 1957). Bipolar has now been adopted into modern psychiatric practice, and replaced the term 'manic depression.'

Diagnosis

There are two widely recognized contemporary classification systems in use worldwide for depression: the ICD-10 (WHO, 1992) and DSM-IV (APA, 1994), both of which have new versions due out in the near future. Operational definitions are provided for clinical and epidemiological research.

Table 1 shows the similarities and differences between the two main classification systems. Both systems have categories for single and recurrent episodes, and both have a category

Figure 1 Vincent van Gogh. Orchard with blossoming apricot trees. Painting, Oil on Canvas. Arles: March 1888. In Van Gogh Museum, Amsterdam.

Table 1 Classification of mania/bipolar disorder

ICD-10	*DSM-IV*
	Hypomanic episode
Manic episode	*Manic episode*
● Hypomania	● Mild
● Mania, without psychosis	● Moderate
● Mania, with psychosis	● Severe
	● Severe with psychosis
Bipolar affective psychosis	*Bipolar I and II disorders*
● Currently hypomanic	● Current (or most recent episode)
● Currently manic (with/without psychosis)	● Hypomanic
● Currently depressed (mild, moderate, or severe)	● Manic[a]
● Currently mixed	● Depressed
● In remission	● Mixed[a]
Cyclothymia	*Cyclothymic disorder*

[a]Excludes bipolar II disorder.

for cyclothymia, as a persistent instability of mood involving periods of mild depression and mild elation, but neither being severe or prolonged enough to meet the criteria for bipolar. Also both systems divide mania into whether or not it features with psychotic symptoms. In the ICD-10 (WHO, 1992), the authors write that people with cyclothymia may not come to the attention of medics, as the elevated periods may well be enjoyable to the individual.

Hypomania is more persistent (of at least 4 days) and more marked than the elation experienced in cyclothymia, but there are no hallucinations or delusions, and the symptoms do not tend to lead to a severe disruption of work or social rejection.

This is in contrast to mania, where normal social inhibitions are lost, and there is marked distractibility. This is in addition to the usual core symptoms of elation, increased energy (resulting in overactivity), pressure of speech (characterized by uninterruptability), increased self-esteem and optimism, and decreased need for sleep. There is a tendency to embark on extravagant and dangerous schemes, spend money recklessly, and make some inappropriate amorous advances. The episode should last at least 1 week before a diagnosis is made. If psychosis is present, it usually takes the form of delusions of grandiosity (e.g., having superpowers, being extremely wealthy, or related to royalty). Persecutory or religious delusions can also be present. 'Flight of ideas' can be present, whereby the individual flits from topic to topic with a tenuous connection, often ending up on an answer far removed from the question asked. Sims (1995) describes an example of flight of ideas in his book, of a female patient saying: "They thought I was in the pantry at home … Peekaboo … there's a magic box. Poor darling Catherine, you know, Catherine the Great, the fire grate, I'm always up the chimney. I want to scream with joy …. Hallelujah!" In severe cases, there may be a neglect of self-care, and of eating and drinking, and they may be placing themselves at risk from and to others.

A diagnosis of bipolar requires at least one depressive episode and at least one manic or hypomanic episode. DSM-IV further separates bipolar into:

- Bipolar I – where mania has occurred on one occasion
- Bipolar II – where hypomania has occurred (but not mania)

A 'mixed' episode of bipolar disorder can occur where a depressed mood may be accompanied by days or weeks of overactivity and pressure of speech; or conversely, a manic mood to be accompanied by agitation, loss of energy, and libido. Sometimes depressive symptoms and hypomanic or manic symptoms may alternate day to day or even hour to hour. According to the ICD-10, a diagnosis of mixed bipolar disorder should be made if the two sets of symptoms are both prominent for the greater part of the current episode, which should last at least 2 weeks (DSM-IV requires the episode to be at least 1 week).

Rapid cycling disorder can occur with both bipolar I and II disorders, and the diagnosis is made where there are at least four affective episodes (i.e., major depression, mania, hypomania, or mixed mood disorder) in the previous 12 months. Rapid cycling is more common in women, and unfortunately has a poorer response to treatment such as with lithium.

Any assessment of bipolar disorder needs to include the following:

- Detailed history of the episode (symptoms, presence of hallucinations or delusions, collateral history if possible)
- Any previous episodes of mania or depression
- Any suicidal or homicidal thoughts
- Any self-neglect
- Family history
- Substance misuse, smoking, and alcohol intake
- General physical health

In addition one needs to rule out the following that can present in similar ways to bipolar, but should not be misdiagnosed as such (Smith et al., 2011):

- Hyperthyroidism or hypothyroidism
- Anorexia nervosa
- Cerebrovascular event
- Dementia
- Other psychiatric disorders, for example, schizophrenia
- Acute drug withdrawal or illicit drug ingestion

Sims (1995) describes in his book about how the manic patient "looks at his world with complete, unshakeable, and wholly unjustified optimism." The person with mania frequently does not have insight into the illness, meaning that when others try and help slow things down, it often manifests in what Sims calls 'manic irritability', when "he feels all his brilliant ideas are frustrated by the lack of vision of everyone else" (Sims, 1995).

Epidemiology

Males and females are equally affected in bipolar disorder (but not in rapid cycling), in contrast to depression, which is more common in women. The lifetime prevalence of bipolar disorder varies from 0.3% to 1.5%. The average age of onset in Western countries is around the mid-20s, although the most common age of onset is the late teenage years, 15–19 years (Joyce, 1984). The second most frequent age range of onset is 20–24 years. Late-onset bipolar disorder is rare but it does occur.

Interesting Yutzy et al. (2012) report an increase in the prevalence bipolar affective disorders I and II, where from

mid-1970s to 2000 it ranged from 0.4% to 1.6%, and by the late 1990s to the 2000s, it had climbed from approximately 5% to 7%.

Course and Prognosis

Manic episodes last between 2 weeks and 4–5 months in bipolar disorder, although over the course of the disorder, there are many more episodes of depression than mania. Ninety percent of patients would experience more than one episode of mania. As patients become older, the time between episodes becomes shorter in duration. Unfortunately, only 20% achieve 5-year stability with good social and personal outcome (NICE, 2006).

According to Abreu et al. (2009) 25–56% present at least one suicide attempt during their lifetime and 15–19% die from the attempt. Lithium has been shown to reduce the risk of suicide and number of suicide attempts in bipolar disorder, but is less effective in rapid cycling bipolar disorder, which has a poorer prognosis (Tondo and Baldessarini, 2009).

There is an association between bipolar disorder and premature death. In a national cohort study of 6618 adults with bipolar disorder, Crump et al. (2013) found that those with bipolar disorder died about up to 9 years earlier on average than the rest of the population. They died prematurely from multiple causes, including cardiovascular disease, diabetes, chronic obstructive pulmonary disease, influenza or pneumonia, unintentional injuries, and suicide.

Several factors have been reported to indicate a better or worse prognosis for bipolar (Soreff and Ahmed, 2014).

Factors suggesting a worse prognosis include the following:

- Poor job history
- Alcohol abuse
- Psychotic features
- Depressive features between periods of mania and depression
- Evidence of depression
- Male sex

Factors suggesting a better prognosis include the following:

- Shorter manic phases
- Late age of onset
- Few thoughts of suicide
- Few psychotic symptoms
- Few medical problems

Etiology

Genetic Factors

Bipolar disorder is one of the most heritable of all psychiatric disorders. There is a genetic component to bipolar disorder, and the literature suggests the involvement of the following genes: ANK3, CACNA1C, and CLOCK genes (Sklar et al., 2008; Ferreira et al., 2008). These genes are thought to make someone susceptible to bipolar disorder, but like many other psychiatric disorders, there are other environmental factors that come into play. Further evidence of the gene–environment hypothesis comes from twin studies, where there is a concordance of 33–90% for bipolar I in identical twins (Soreff and Ahmed, 2014). If genes were the only etiological factor, one would expect 100% concordance as they share 100% of their genes. Conversely, adoption studies show that environment alone is also not the only factor. Children whose biologic parents have either bipolar I or a major depressive disorder remain at increased risk of developing an affective disorder, even if they are reared in a home with adopted parents who are not affected (Soreff and Ahmed, 2014).

A child of a parent with bipolar disorder has a 50% chance of having a major psychiatric disorder. First-degree relatives of people with bipolar I are approximately 7 times more likely to develop bipolar I than the general population (Soreff and Ahmed, 2014).

Biochemical Factors

Certain drugs such as cocaine that increase the levels of monamines (dopamine, serotonin, norepinephrine) in the brain can precipitate mania. Some authors have implicated the neurotransmitter glutamate in the etiology of affective disorders, and postmortems looking at the frontal lobes of those with affective disorders have shown elevated levels of glutamate (Hashimoto et al., 2007).

The hypothalamic–pituitary–adrenal (HPA) axis is a regulatory system that integrates neuronal and endocrine function, and manic and depressed bipolar individuals appear to have a dysregulated HPA axis. The HPA axis is linked to the serotonin system, sleep disturbance, and cortisol secretion. Exploring this further may give rise to other novel treatment strategies.

Neurophysiological Factors

A decrease in gray matter, a decreased activation in certain brain regions, and an increased activation in other regions (such as the ventral limbic area that mediate and generate emotional responses) have been discovered (Houenou et al., 2011), although more research in this area is needed.

Psychodynamic Factors

Melanie Klein proposed that mania was a defense against depression, and certain personality characteristics may be present in those with bipolar disorder (disturbances in neuroticism, extraversion, and openness) (Barnett et al., 2011). A dysregulation of self-esteem, childhood trauma, and abuse have been proposed as etiological factors for bipolar disorder (Leverich et al., 2002).

Environmental Factors

The gene–environment hypothesis dictates that the genes make an individual susceptible to the disorder, and the environment acts as an additive to cause the disease; different researchers have proposed differing amounts of interaction between the genes and the environment. A stressful circumstance can often act as a trigger for bipolar, and these could include relationship breakdown, abuse, death of a loved one, physical illness, prolonged sleep disturbance, or accumulative stress related to money, work, or relationships.

Cultural Factors

In the UK, Afro-Caribbean immigrants have been found to be at a greater risk of presenting as manic than their Caucasian counterparts (van Os et al., 1996), although this could be due to the stress of immigration or racial prejudice. In Figi, a condition called 'matiruku' has been reported, described as a 'periodic insanity' (Price and Karim, 1978). It is characterized by increased talkativeness, increased psychomotor activity, elated mood, a decreased need for sleep, and occasional violence. These episodes would occur at the same time every month, or every year, and would last about 2–7 days. Diagnoses could be influenced by the self-report of individuals belonging to certain communities, giving skewed data. For example, in Amish communities, overly inflated self-esteem is considered to be a grave sin. In both prospective and retrospective studies carried out in China and Israel in individuals with bipolar disorder, there has been a preponderance of recurrent manic episodes over depressive episodes. This is the opposite to what has been found in other areas across Europe and other Western countries. Some authors suggest that climactic factors may play a part in the course for bipolar disorder (Sanches and Jorge, 2004).

Treatment and Management

The following is largely based on the current National Institute for Health and Clinical Excellence (NICE) guidelines in the UK for adults, children, or adolescents with bipolar disorder (NICE, 2006), and the Evidence-based guidelines for treating bipolar disorder: revised second edition from British Association for Psychopharmacology (Goodwin, 2009). NICE provides national guidance and advice to improve health and social care, and the recommendations are based on the best available evidence, also taking into account of cost–benefit ratio.

Non-pharmacological Treatment

Of paramount importance is the need to establish a trusting therapeutic relationship between the individual with bipolar, and the carers and health-care professionals. The following are examples of non-pharmacological treatments that can help in bipolar (Patient.co.uk, 2012).

- Education regarding diagnosis, treatment, and side-effects
- Good communication
- Self-help groups
- Support groups
- Self-monitoring of symptoms, side-effects, and triggers
- Coping strategies
- Psychological therapy
- Encouragement of engagement in calming activities
- Telephone support
- Diet – adjunct use of omega-3 fatty acids could help bipolar depressive but not bipolar manic symptoms (Sarris et al., 2012)
- Regular exercise
- Psychological interventions such as cognitive behavioral therapy and supportive psychotherapy (Goodwin, 2009)

Pharmacological Interventions

Treatment of Acute Manic or Hypomanic Symptoms

The drug treatment of an acute manic or hypomanic episode depends on the severity of symptoms and clinicians should be guided by current medication doses and previous response (NICE, 2006). When the NICE (2006) guidelines were written only lithium, olanzapine, quetiapine, risperidone, and valproate semisodium were licensed for the treatment of acute mania in the UK. Lithium, olanzapine, or valproate should be considered for long-term treatment (2–5 years depending on risk factors) of bipolar disorder. Lithium requires monitoring of levels and monitoring of renal and thyroid function.

Pharmacological agents approved by the FDA, however, for use in treating bipolar disorder are as follows (taken from Sorref and Ahmed, Medscape, updated 2014):

- Valproate (manic)
- Carbamazepine, extended-release (manic, mixed)
- Lamotrigine (maintenance)
- Lithium (manic, maintenance)
- Aripiprazole (manic, mixed, maintenance)
- Ziprasidone (manic, mixed)
- Risperidone (manic, mixed)
- Asenapine (manic, mixed)
- Quetiapine (manic, depression)
- Chlorpromazine (manic)
- Olanzapine (manic, mixed, maintenance)
- Olanzapine–fluoxetine (depression)

Figure 2 shows the initial treatment plan for mania or mixed bipolar episode as devised by the British Association of Psychopharmacology (Goodwin, 2009).

Management of Depressive Symptoms

This is the same as in the management in unipolar depression, and is included in the articles on depression and antidepressants, and hence has not been included here. Of note, however, there is a risk of switching to a manic episode with antidepressants, and thus caution is advised and careful monitoring is necessary. In bipolar, antidepressant may not be as effective, and a combination therapy (antidepressant with an anti-manic agent) may be required.

Management of Acute Mixed Episodes

NICE (2006) advises that antidepressants should be avoided, and prescribers should consider treating patients with an acute mixed episode as if they had an acute manic episode (see above). Patients should be monitored closely for risk of suicide.

Management of Rapid Cycling

Previous treatments need to be reviewed, and the prescriber needs to check for compliance with medication. If they are on antidepressants, then this needs to be stopped. Thyroid function should be checked, and anti-manic therapy will need to be optimized. Lithium and valproate is used first line, but if this does not work, lithium can be trialed on its own (NICE, 2006). Lithium levels would need to be

Figure 2 Evidence-based guidelines for treating manic or mixed bipolar episode. Goodwin, 2009.

checked, as both lithium withdrawal and lithium toxicity can cause rapid cycling. Psycho-education (in addition to keeping a 'mood diary' detailing aspects of their symptoms, when they occur and anything that helps) should be encouraged. The focus should be on optimizing the long-term treatment instead of focusing on each individual episode. Medication trial should last for more than 6 months (NICE, 2006).

Electroconvulsive Treatment in Bipolar

Electroconvulsive treatment (ECT) should only be considered in severe cases, with the aim of obtaining short-term and quick resolution or improvement of the symptoms. ECT should be used only when pharmacological and psychological treatment has been tried and failed. ECT can also be used if the situation is thought to be life threatening in those with severe depression, catatonia, or a prolonged or severe manic episode (NICE, 2006). The effects of ECT are thought to be short-lived.

Summary

In recent times, more people in the media and public eye are declaring their diagnoses of bipolar. This has undoubtedly increased the awareness of the condition, with a hoped decrease in stigma. Some have emphasized the positive aspects of having bipolar; for example there is evidence that it is strongly correlated to creativity and literacy (Santosa et al., 2007). Others who have experienced bipolar have commented on the enjoyable experience of having the increased energy and mood during the elated phase. This has even had the effect of a perceived increase in individuals coming to their health care specialists with a self-diagnosis of bipolar, which could be due to the increased awareness, and decreased stigma, but may also be due to the "lay person's aspirations for higher social status, as illustrated by the implicit association of bipolar disorder with celebrity status and creativity" (Chan and Sireling, 2010). The question arises about whether some of the successful people we see with bipolar would have been as talented if they did not have their illness. In one of his last letters van Gogh wrote: "If I could have worked without this accursed disease, what things I might have done." The treatment available today was not present then, and we simply do not know if his brilliance as an artist was because of his mental illness or in spite of it. What we do know is that the world is undoubtedly better off for having his paintings.

Abstract

Michael Mann is a comparative-historical sociologist whose main work is the four volume 'Sources of Social Power.' This work provides a sociological history from the beginning to the present day, giving an account of long-term patterns of ideological, economic, and military power conceived of as overlapping and intersecting socio-spatial networks. He is particularly well-known as a political sociologist.

Michael Mann is a comparative-historical sociologist best known for the four volumes of his 'Sources of Social Power' (1986, 1993, 2012, 2013a, henceforth 'Sources'). This four volume work spans history from ancient times to the present day, distinguishing between four main types of power: ideological, economic, military, and political. Mann charts the course of these four types of power, conceived as networks, at the leading edges of social development across time and space. His approach to understanding social change, analyzing major macro-patterns in society over time, updates the tradition of the classical sociological theory of Marx and Weber. Like the works of these classical theorists, 'Sources' deals, as it moves to the present, with the origins and trajectories of modern capitalism; and this question is also still central to sociologists interested in tackling social change from a macro-historical perspective.

Mann was born in 1942 and grew up outside of Manchester in lower middle-class circumstances (Hall, 2006). He did an undergraduate degree in history at Oxford University and continued there to do his doctorate with an empirical study about industrial workers. At this time, the late 1960s and early 1970s, there was much debate about the role of ideology and class consciousness among the working class. Mann argued, in his first major journal article (1970), that ideology did not provide the 'glue' of capitalist society, nor did the alienation of workers indicate the potential for revolutionary change. This is one background to his sociology. The second was the idea, prevalent in Marxist sociology at that time, that the role of the state, which lacked autonomy, was to legitimate the economic conditions of capitalism. This idea, again, was rejected by Mann (1984) when he argued that the state came to constitute an autonomous source of power, operating differently from other sources by exercising centralized control over a particular territory, with its own dynamic.

While Mann's early work developed against the background of Marxist sociology and he departed from some of its main tenets, his politics have consistently been on the left or radical end of the spectrum. The Marxist debates, which continued into the 1980s, are now largely forgotten, displaced in the social sciences by the 'cultural' turn. Yet Mann started writing 'Sources' at a time when the major figures in social thought were the Neo-Marxists and Frankfurt School thinkers – or their positivist opponents. He taught sociology at the University of Essex in the 1970s before spending most of the subsequent decade at the London School of Economics, where at the time Ernest Gellner (1988) and John A. Hall (1986) were also working on sociological histories of power. They jointly and for many years convened a seminar called 'Patterns of History,' to which they invited a wide range of speakers from across the social science disciplines. This seminar was used to inform their comparative-historical analyses. The synthesis of many fields, including archaeology, ancient history, and anthropology, was evident in the first volume of 'Sources,' published in 1986, and has been in evidence throughout Mann's work. Mann then moved to the department of sociology at the University of California, Los Angeles in 1987, where he has remained since.

Apart from 'Sources,' Mann has written about geopolitics and the threat of nuclear war during the height of the Cold War in the 1980s (1988a), a comparative analysis of 'Fascists' (2004), and 'The Dark Side of Democracy' (2005), about the major instances of ethnic cleansing – including the aftermath of the breakdown of the Soviet Union and subsequent Balkan wars and the war in Rwanda in the 1990s. He also wrote 'Incoherent Empire' (2003; see also his conversations with John Hall, Mann, 2011), criticizing American foreign policy against the backdrop of the wars in Iraq and Afghanistan in the 1990s and 2000s. But apart from these forays into other topics, his main work has been 'Sources.' Now that this is completed with the final volume, subtitled 'Globalizations' (2013a), he has brought his account of the development of power up to the present day. And although he is planning further work refining and drawing out the implications of 'Sources,' these four volumes provide an indepth sociological account of the shape of history.

It is impossible to present anything more than a few arguments from the four volumes, which together run to more than 2000 pages. Before doing so, it is worth briefly elaborating the conceptual apparatus of 'Sources.' First, Mann thinks that societies are not 'systems' or unified wholes; rather 'societies are constituted of multiple overlapping and intersecting socio-spatial networks of power' (1986: 1). This implies that networks of power have different spatial extents or reaches: for example, the reach of contemporary American military power is global, even though it also confronts other military powers; and this network is different from the reach of capitalist markets, which cover even greater geographical reaches of the globe; and different again from political economies of welfare, which are confined to nation-states. Secondly, power, apart from being of four types, is not just 'power over,' or the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61240-0

'distributive' power of A over B (as Weber argued), but also 'power through,' joint power over third parties or over nature, which (following Parsons) Mann labels 'collective power' (1986: 6).

Thirdly, power is also divided into extensive versus intensive, and can be authoritative or diffused. These distinctions concern the organizational reach of power (1986: 9), and Mann gives the following examples for the combinations of each of these four: an army command structure is authoritative/intensive (tight control over troops), whereas a militaristic empire is authoritative/extensive (control over far-flung territories). A general strike is intensive/diffused (generating strong but not concentrated solidarity) and market exchange is extensive/diffused (consisting of lots of indirectly connected interactions over large spaces). These distinctions allow him to characterize the socio-spatial networks of all four sources, including the most geographically dispersed macro-relations of civilizations and empires; however, Mann also shows that the most spatially circumscribed power containers can provide solidarity for workers in factories or impose control over troops ranged on battlefields.

Against this background, it is possible to present some of the main arguments in the four volumes, with a particular focus on where they place Mann in contemporary sociological debates. Volume One, subtitled 'A history of power from the beginning to AD 1760,' culminates in his explanation of "the rise of the West" but it begins with the emergence of the settled societies in ancient Near East, where the need to protect an agricultural surplus required centralized power – or the 'caging' of people within a territory subject to centralized political authority. This prefigures the importance of military-cum-political power in his work, as opposed to economic class relations. Mann does not ignore the dynamics of class, especially in his account of the Greco-Roman world. But his explanation is also more state-centric, and remains so throughout the four volumes. Indeed, he is most closely associated with the 'state-centered' (Collins, 1999) school of Jack Goldstone, Theda Skocpol, and Charles Tilly, who argue that war and the preparation for war and the resulting increase in state capacity is central to the understanding of the rise of the West. This school has concentrated on modern Europe, but Mann's analysis of the military source of power also extends to other parts of the world and to other periods.

Like other 'state-centered' theorists, Mann argues that military technologies are often at the leading edge of increases in social power. Yet he does not focus on technology per se, but rather on how it organizes power in socio-spatial networks. One example is that technology controls the logistical reach of military power, such as the need to supply transport animals with food (1986: 134–142). This allows him to argue that this reach was more limited than is commonly thought. The role of the socio-spatial organization also sets his explanation of the rise of the West apart from other power networks. A key factor here, on which Volume One ends is the role of ideology, in the shape of the 'normative pacification' provided by medieval Christendom (1986: 506). Here Mann departs from Weber's explanation which focused on Protestantism and on the individual's ethic of asceticism. Instead, Mann's explanation centers on the integrating organizational force of Catholicism in late medieval Europe.

Another departure here from Weber is that although he devotes a chapter to an excursus into comparisons with the other world-religions, Mann argues that the evolution of power is more important than a comparison to ascertain which of the major civilizations achieved a breakthrough. In other words, it is more important to explain how the leading edge of power has moved on a path of increasing over time – rather than explaining why it increased in one place (the West) and not in others (the more stable 'rest'). This, too, sets him apart from other social thinkers. If we fast-forward to the present day for a moment, we can see that there is an advantage to Mann's approach in analyzing different spans of power over different periods of time: his framework whereby the spatial organization of military power is separate from the reach of economic power means that he is able to argue that the United States can remain the globally dominant military power for several decades to come – even when the leading edge of economic power may have shifted elsewhere, and particularly toward East Asia. In other words, one type of power can still be 'leading' even while other powers undergo comparative shifts.

Volume Two of 'Sources,' subtitled 'The Rise of Classes and Nation-States, 1760–1914,' concentrated on the role of the state during the nineteenth century, which covers the period from the French and American Revolutions to the First World War. The two revolutions are also the second major instance in history, apart from the unifying role of the church in the Middle Ages, of the leading role of ideological power. The third major ideological influences were in the twentieth century – the Fascist and Communist revolutionary ideologies. For the nineteenth century, a lasting contribution of Volume Two is the detailed account of comparative state capacity. Mann argues that especially in the late nineteenth century, some states expanded their infrastructural power more rapidly than their despotic power, where infrastructural power is the collective power of the state "through" society "coordinating social life," whereas despotic power entails the distributive power of state elites over civil society (1993: 59). The analysis is based on detailed data that he compiled about state spending, which shows that in some states more than others, civilian spending increased faster than military spending, which had previously been the bulk of state spending.

His account of the nineteenth century is therefore unique in giving pride of place to the state: the dominant accounts of this period focus on the industrial revolution and on technological innovations. Mann, in contrast, argues that in this period, the state caged citizens into nation-states, and these nation-states then went on to become collective actors internationally, with rival ideologies and political economies, in the twentieth century. Still, at the core of Volume Two is therefore a puzzle (recalling that Mann's explanation is state-centered and focuses on military competition): this was a relatively peaceful period in world history, yet it was also a period in which state capacity increased at an unprecedented pace. This puzzle can be resolved when it is recognized, first that the increase was mainly in infrastructural rather than despotic power. Mann thus departs from Tilly (1990) in highlighting the reduced contribution of the state to the military and its increasing role in creating

civilian infrastructures. Secondly, states took on quite different shapes during this period, some (Germany, Russia) becoming more state-centric, while in others (Britain, the United States) markets played a greater role. It can be added that although the nineteenth century was relatively peaceful in Europe, this can be contrasted with the often violent European conquests of colonies and by the settler states in America and Australia. In any event, the division of major powers into at least two kinds of states paves the way for explaining authoritarian paths in the twentieth century.

Volume Three, subtitled 'Global Empires and Revolution, 1890–1945,' goes back into the nineteenth century to revise Mann's account in the earlier volumes somewhat. Mann now argues that empires, which he did not discuss in Volume Two, become central to the twentieth century. Thus apart from the two authoritarian paths prefigured in the nineteenth century, Volume Three charts the rise and fall of the British, Japanese, American, and other empires. Imperialism also enabled Mann to add racism as a major modern political ideology. In Mann's account of the struggle between rival empires, there are echoes of the 'state-centered' school. However, Mann also thinks that the World Wars represent a culmination of intra-European warfare, with the conflict between Japan and China added in the Second World War. However, the result of the wars was the end of European imperial dominance. This was partly due to the contradiction between a racist ideology, which denied rights to colonial subjects, coupled with the need to use soldiers from the colonies during the World Wars, in turn fueling their nationalism. These factors contributed to the downfall of the colonial empires after the Second World War – except for the American empire, where the racism of denying rights to African-Americans had been a feature of domestic politics rather than of America's overseas engagements.

Another place in Volume Three where Mann departs from conventional ideas is in his explanation of the Great Depression, where he focuses not just on finance (as many others do), but rather on a series of underlying tensions: first, in geopolitics, there was a lack of international cooperation resulting from the First World War, partly due to the vacuum left because Britain no longer played a hegemonic role and the United States was not yet willing to take on this role. Secondly, in agriculture, there was overproduction and consequently, not enough demand for the new consumer goods that could now be mass produced. This approach to understanding an economic crisis by reference to deeper structural causes, also marks Mann's explanation of the Great Recession of 2008 in Volume Four, which was not just caused by financial markets but also by the lack of consumer demand in societies, especially the Anglophone ones (the United States, Britain, and other English-speaking countries where economic power is comparatively stronger than the other state), partly due to increasing inequality and with it the lack of broad-based consumer demand (the few rich are not intensive consumers). This underlying factor contributed to financial instability, ultimately affecting whole economies. Still, the lack of widespread demand and its resulting inequalities meant that the 2008 Great Recession affected the (white) Anglophone countries the worst, just as the Great Depression could be labeled the 'Great White Depression' (2013b: 78) since it mainly affected Europe and North America; other parts of the world were affected only as these crises rippled outwards.

Volume Three also continues the explanation of the divergence between different kinds of capitalist welfare states (this was already prefigured in Volume Two). A major argument here is that the United States was in fact on course to a welfare state during the 1930s, just as other countries were. Put differently, it was not yet on an exceptional course. Instead, there was under Roosevelt a compromise between capitalists and workers which created employment rights and some social insurance as a means to counteract the effect of the Depression. In Sweden, in contrast, which is often seen as the quintessential model of welfare state development, the development of the welfare state was still embryonic at this time. Here again war played a decisive role for the United States: after the Second World War, since there was a boost to economic growth and little unemployment; only a weak welfare state emerged in the United States, which confined benefits to soldiers (as opposed to other European powers, where whole societies had waged war, and so more universal welfare states were created). Thus, at the end of Second World War, with highly progressive taxation and a large state that was mobilized for the war effort no longer needed in America – unlike in other countries where a stronger state was required for economic recovery and where citizens also had to be rewarded for their war efforts – the American welfare state got off to a comparatively weak start. It can be seen that war and military power, for the most part overlooked by sociologists, is a distinctive feature of Mann's sociology, and it can play a positive as well as a destructive role.

To explain the different paths of welfare states, Mann draws on T.H. Marshall's concept of citizenship. Mann uses the three types of citizenship – civic, political, and social – to analyze the rights that people obtained from the ruling classes within the nation-state (1988b). Thus he goes beyond explaining conflict in capitalist societies solely by reference to economic classes. The paths whereby these rights were achieved now define the varieties of capitalism. But while civil and political rights have been gained across democratic nation-states, the inclusiveness and depth of social citizenship differs substantially across Western democracies and beyond. As we have seen, war has played a major role in the trajectory of citizenship rights. Another example here could be how women's suffrage (political rights) was achieved early in White Settler societies, where women had stronger roles in the conquest of the frontier; and after the First World War political rights were expanded to include women in countries where they had substantially supported the war effort. Again, an interesting implication is that unless there is either a major upheaval, such as war or a crisis that impels classes or other social groups to seek change in the social contract, these rights will not be extended further. This partly accounts for Mann's rather pessimistic view that social citizenship rights have stalled in recent decades, leaving the varieties of citizenship regimes intact.

After the end of Second World War, only two empires remained and since the end of the Cold War, only one has been left. In Volume Four (2013a), four of thirteen chapters are devoted to American empire and American exceptionalism; and America plays a large part in several other chapters as well.

There are many others who have written about American empire or America's role in the world; and here too Mann departs from other views inasmuch as he focuses on the military power of the United States, rather than on how empire is driven by the needs of capitalism to protect or expand markets (as posited by Marxists and world-systems theorists). Further, he carefully weighs the benefits and costs of the American 'informal' empire (as he does with the other empires in Volumes Three and Four); and while there have been some benefits to the United States, especially since the dollar has been the world's reserve currency ('seigniorage'), on balance, maintaining a military empire has been a drain on American power. The United States has nevertheless also had some gains from informal empire, including the facility of being able to run large trade deficits in return for the security provided for its military allies. The balance sheet of those at the receiving end of American domination abroad, on the other hand, has been much more negative. Several countries that were fought over *during* the Cold War were decimated by American military power; and Iraq and Afghanistan have had the same fate *after* the Cold War, when the United States has been the only developed democracy initiating interstate wars.

Another chapter in Volume Four that deserves to be highlighted is on climate change, where a key part of Mann's explanation is the rise of consumer citizenship. At a time when social citizenship (or the welfare state) is only being defended rather than deepened by the major powers, it is also being displaced by the idea that the benefits of market growth is among the basic rights of citizens – as consumers. This type of citizenship is taking hold not just in the West, but also in China, which, together with America, must be part of any solution for the mitigation of the potentially disastrous consequences of climate change. These two powers have the largest economies (and the United States also has military power), while the parts of the Global South, which are most adversely affected by climate change, have little power in either sense. Mann argues that the solution to this crisis will be political, with agreement between the world's nations not to focus so much on growth and economic benefits, curbing capitalist profit; as well as from the side of citizens as consumers. In other words, the solution will involve the most powerful institutions in the twentieth and twenty-first centuries – nation-states, capitalism, and citizenship. Yet we have already seen that the weaknesses of economies based on consumer demand contributed to the Great Recession of 2008, when there was not a large enough base of prosperity to sustain growth, due to increasing inequality. Here of course there is a contradiction, since growth is needed to avoid severe economic downturns – and yet is also environmentally disastrous.

The focus on empires, as well as on nation-states and capitalism, are also the key to Mann's thinking about 'globalizations.' He pluralizes the term in the subtitle for his fourth volume because all three of these (empires, nation-states, and capitalism) have become globalized in the course of the twentieth century. Capitalism won out over rival ways of organizing economies, particularly state-directed ones, and even though there are still varieties of capitalism, market-capitalism has extended to most parts of the globe. The nation-state has also become the norm across the globe: here, of course, there is great variety, but nowadays, states are only legitimate when they represent their people. The definition of people (or citizens) in terms of a hierarchy or exclusiveness of races (as with the Fascist powers) was defeated in the Second World War, and only China among the developed societies still has a single-party state claiming to represent the interests of its people. Otherwise, the model of democratic nation-states has spread throughout the North and beyond. Finally, although empires competed with each other and thus fractured the globe before the Second World War, they were consolidated into two factions during the Cold War; and now all that remains is the American informal economic empire shielded by the global reach of its military power. Although another global force and crisis, climate change, and possibly yet another, nuclear war (as Mann notes, in keeping with the centrality of military power in his work), threaten the world, political and economic globalizations are still ongoing.

In bringing 'Sources' up to the present, Mann offers a sophisticated theory of globalization. His final two volumes set him apart from other sociologists in providing a multidimensional account of contemporary capitalist democracies. Most other accounts of globalization and of contemporary capitalism are reductionist in focusing primarily on the economic dimension. Mann is also among the few sociologists to incorporate military power as part of his overall analysis rather than within the subdiscipline of military sociology or within international relations. The same goes for his analysis of climate change, which goes beyond the sociology of the environment or of risk. At the same time, Volumes Three and Four also engage with mainstream debates in sociology, especially in analyzing the varieties of capitalism (or 'political economy'), and also in social movement theory and theories of revolution. As we have seen, Mann's addition of military power plays a crucial role, for example, in his account of the varieties of capitalism and his explanation of why the American welfare state did not grow like the others.

Mann's work is also unique in focusing attention on the nation-state, arguing against the idea of its demise, which is popular among globalization theorists. Instead, his multiple 'globalizations' have different spatial reaches and the four sources of social power also operate differently: for example, while the political power and social citizenship rights of workers are 'caged' by the authoritative power of the nation-state, the diffuse economic power of capitalists, on the other hand, and especially of finance capital, is at least partly transnational. Hence Mann argues that the four sources have become 'orthogonal' to one another, which has benefits in avoiding dangerous concentrations of power, but also drawbacks insofar as it can result in stalled social development. In any event, Mann's sociology is distinctive in theorizing the transnational or global level, not just with military power, but also in charting shifts, for example, in the economic power of financial capital.

While Mann rejects deterministic accounts of social change which rely on a single source of power, he nevertheless wants to provide an encompassing theory. Yet a major current in recent social thought has been to argue against such encompassing theories or 'grand narratives.' And it is noteworthy that there have recently been no sociological theories or analyses of the macro-social processes of a scope similar to Mann's 'Sources.'

As we have seen, his grand narrative (if it can be called that) departs in important ways from other analyses of states and economies. At the same time, his four sources, operating differently and across different spatial extents over various periods, do not make for a single reductive story about the evolution of society. Thus one criticism of his work is that he is too historical and not analytical enough. And it is true that there is no single central thrust to his anatomy of contemporary social change. Perhaps the main reply to this criticism is that with globalizations, the processes of social change have become very complex, and only a multidimensional and deeply historical analysis can give this complexity its due.

Another way to highlight the distinctiveness of his sociology is to contrast him with other contemporary social theorists: Mann rejects Neo-Marxist or world-systems theories which see American empire as a way to secure capitalist interests across the globe. This puts him at odds with thinkers such as Wallerstein (2013), who foresee the demise of American power with a shift to economic power to Asia, and China in particular. For Mann, capitalism is not the only force determining social change, and thus American military power can remain unrivalled for decades to come, even while its economic power wanes. Yet Mann also rejects liberal thinkers like Gellner (1996) and Hall (2013), who think that the diffusion of capitalism and civil society (or the growth of middle classes) will, in due course, yield less authoritarian regimes. Mann, in contrast, thinks that there is a variety of capitalisms, and some with stronger states – including single-party China – have coped better with the recent economic crisis while at the same time being on a path toward greater economic inequality.

Another contrast that can be made is with international relations thinkers, who are split into realists and liberals. Realists would focus on the geopolitical or military interests of the United States, ranged against the rise of the new military power, China, in the East. Liberals would prioritize how the US and its allies continue to uphold a binding normative order that promotes democratic regimes and opens markets bringing economic growth. Yet Mann wants to see military power not as a separate order of interstate relations but analyzes these relations in terms of the positive and negative impact they have on domestic social development. At the same time, it is not just norms that uphold the international order, nor does economic growth diffuse evenly with open markets: there are also power imbalances in how financial regimes are imposed on the global South and economic inequalities are growing in some regions even while declining in others (Mann and Riley, 2007). Here, too, Mann departs from the dominant orthodoxies, in this case from the main positions in the field of international relations.

A criticism of Mann's work is that he downplays ideological power (see the chapters by Gorski and Bryant in Hall and Schroeder, 2006). There are three defences against this criticism: first, that ideological power has no force without being mobilized in organizational form, either extensive or intensive. In this respect, his theory can be labeled 'organizational materialism.' Secondly, he has added racist ideology to his explanation of empire and ideology has played a decisive role on a number of historical occasions, including modern revolutions (French, American, Russian, Chinese, and Iranian) and Fascism. Third, in terms of political ideologies, Mann points out that environmentalism is the only major new ideology in the twentieth and twenty-first centuries. Still, it remains that Mann has bucked the recent 'cultural turn' in the social sciences. It is also noteworthy that Mann prefers speak of 'ideological power' rather than 'patterns of culture,' and perhaps it is an open question whether, in addition to the ideologies and occasions when they mattered in Mann's account, it is possible to identify other instances of the force of ideologies in contemporary social change.

A somewhat different question relates to Mann's omission, among of his four sources of social power, of science and technology (or technoscience). Not only his account of the divergence between industrial powers in the West and 'the Rest' during the nineteenth century, but also his account of climate change, raise the issue of where techno-science fits in as a source of power, both in contributing to the rise of the West and also in contributing, separately, to environmental problems (and possible solutions to these). Mann mentions on occasion that science, with its cold explanations and lack of emotional succor (2012: 8), differs from ideological power. But he also argues that technoscience, rather than being independent, has been subservient to the other sources of social power. Nevertheless, it has been argued that without being treated as autonomous, the role of techno-science in his theory is incomplete (see the chapter by Goldstone in Hall and Schroeder, 2006; Schroeder, 2013).

These are just some of the distinctive contributions and criticisms of Mann's sociology. His work, drawing on several disciplines apart from sociology, has been influential beyond sociology and has reached into various social science disciplines. His impact has been particularly pronounced in political sociology, in theories of the state and nationalism, ethnic conflict and empire, and in international relations. His concept of infrastructural power has been used in examining developing societies, where states are often strong in despotic (and military) power, but weak in providing a basis for social development. Finally, in can be mentioned that social historians in particular have drawn on his work since social history has focused on social change 'from below,' a trend which can be also be seen in the current turn to global history, where also, Mann's work has been well received (Osterhammel, 2011).

What we see in his analysis of contemporary social change is not a single model on which societies are converging: rather, there is one dominant military empire, several forms of capitalism, and different kinds of nation-states, including the Chinese party-state and several others. Economic power is now globally capitalist, with capitalist elites having more extensive power while workers are nationally caged; nation-states are stably institutionalized but consist of different types with greater or less concentrations of power and different interests that they represent; and there are now multiple globalizations after the upheavals that fractured the globe in the twentieth century. Mann's main impact is perhaps yet to come: the last two volumes have only been published recently. Comparative-historical sociology has been an area of sociology marked by high-powered debates in the past, a tradition that goes back to Marx and Weber. More recently it has been reinvigorated by figures like Bendix, Tilly, Skocpol, Goldstone, Gellner, and others. This subdiscipline has not perhaps been as influential as it could be in

mainstream sociology or in connecting with other areas of sociology; the main connection with other areas of sociology has been the state. In the twenty-first century, this focus on the state, though now taken beyond the context of the West, is bound to be a key focus in sociology, now ineluctably entwined with global forces. It is inevitable that, barring climate and nuclear disaster, the world will become more globalized in the twenty-first century, with alternative economic and political models competing with each other and facing further crises. In this complex of networks of social powers, Mann's 'Sources' is bound to be an indispensable guide.

Abstract

Karl Mannheim, key classical sociologist, social thinker and founder of the sociology of knowledge, was born 1809 in Budapest, studied and worked there as well as in Heidelberg and Frankfurt, Germany, and died 1947 in emigration in London, England. His *Ideologie und Utopie* (1929) was the most widely debated book by a living sociologist in Weimar Germany and *Man and Society in an Age of Reconstruction* (1940) was no less influential during his life in Britain. His studies of generations, competition as a cultural phenomenon, economic ambition, structures of thinking, sociology of culture, conservatism, and his later writings in political sociology and social planning, mark him out as an ingenious and innovative thinker.

As a classic of sociology, Karl Mannheim is the author of one book, with three lives. *Ideologie und Utopie* (Mannheim, 1929) was the most widely debated book by a living sociologist in Germany during the climactic years of the Weimar Republic; *Ideology and Utopia* (Mannheim, 1936) has been a standard in American-style international academic sociology; and the quite different German and English versions of the book figure in reappraisals of Mannheim initiated by new textual discoveries (Mannheim, 1980, 1984) and republications (Wolff, 1993; Mannheim, 1952, 1953, 1956), fostered by a reopening of questions the discipline of sociology had once deemed closed. Mannheim's sociological theorizing has been the subject of numerous book-length studies, evidence of an international interest in his principal themes (e.g., Barboza, 2009; Corsten, 2010; Endreß and Srubar, 2000; Enebakk, 2000; Gabel, 1987; Kettler and Meja, 1995; Kettler et al., 2008; Kupiec, 2006; Patanè, 2000; Santambrogio, 1990). As a living social thinker, Karl Mannheim was not in fact the author of any work he himself considered a finished book, but rather of some 50 major essays and numerous smaller treatises, many later published in book form. His studies of generations, economic ambition, competition, structures of thinking and similar topics in the sociology of culture, as well as his later work in political sociology, notably on the theme of planning, mark him out as an ingenious and innovative social thinker.

Born on 27 March 1893 in Budapest, the son of prosperous Jewish parents, Mannheim studied philosophy and sociology in Budapest, Berlin, Paris, and Heidelberg, held academic posts at Heidelberg, Frankfurt, the London School of Economics, and the University of London, and died on 9 January 1947 in London. Just prior to his death he was appointed chair of the European division of UNESCO. His biography, one of intellectual and geographical migration, falls into three main phases: Hungarian (to 1919), German (1919–33), and British (1933–47). Among his most important early intellectual influences are Georg Lukács, Oscar Jászi, Georg Simmel, Edmund Husserl, Heinrich Rickert, and Emil Lask. Mannheim was also strongly influenced by the writings of Karl Marx, Max Weber, Alfred Weber, Max Scheler, and Georg Dilthey. Through these and other authors, German historicism, Marxism, phenomenology, sociology late also Anglo-Saxon pragmatism became decisive influences upon his work.

Mannheim spent his first 26 years in Budapest, where he graduated in philosophy and precociously participated in the intellectual life of the 'second reform generation' born a decade earlier. The advanced thinkers of the time were divided between proponents of modernization oriented to French and English social thought and prophets of radical cultural rebirth inspired by Russian and German models. Mannheim did not think that his dedication to the latter group, led by the philosopher Lukács, entailed a blanket rejection of the former, under the sociologist Jászi. Lukács' wartime *Sunday Circle* in Budapest may have devoted its meetings to Dostoevski and Meister Eckhardt, but Mannheim was also a member of the *Max Weber Circle* when he was in Heidelberg, and during a visiting semester in Berlin in 1914 he attended the lectures of Georg Simmel, the subtle mediator between cultural philosophy and sociology.

Mannheim lived in Germany from 1919, when he fled the counter-revolutionary regime in Hungary, until 1933, when National Socialist decrees forced him out of the University of Frankfurt and he left Germany for England. Within a few years of his move from the Budapest intellectual scene to German university life, Mannheim began work on two treatises on the sociology of culture that were only posthumously published as *Structures of Thinking* (1980, 1982) and he completed a habilitation thesis under Alfred Weber, a sociological interpretation of the rise and self-differentiation of conservatism with the programmatic subtitle *A Contribution to the Sociology of Knowledge* (1925). Its submission coincided with Mannheim's publication of an article devoted to his critical encounter with Max Scheler, who recently had brought the concept of the sociology of knowledge into discussion. Mannheim's inaugural address as university teacher (*Privatdozent*) at Heidelberg set out the parameters of 'the contemporary state of sociology in German,' dealing with Weber, Troeltsch, and Scheler. Sociology, he believed, provided the frame of reference for twentieth century thinking as a whole.

Mannheim's aloofness, however, from the specialized 'state of sociology' question, as well as his equation of the main currents of contemporary thought with the leading sociological theories, indicate that his move from philosophy to sociology cannot be understood as a simple change of academic

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61084-X

specializations. Sociology, in his view, was a more comprehensive undertaking than the academic discipline still taking form. Goaded in 1929 by a charge of 'sociologism' against *Ideologie und Utopie* by the noted literary scholar, Ernst Robert Curtius, Mannheim (Meja and Stehr, 1982, 1990) again invoked the heritage of Weber, Troeltsch, and Scheler against the literary scholar's accusation of treason to humanism, presenting these sociologists as modern German classics, as 'a great heritage, a tradition that must be built upon.'

The novelty in Mannheim's approach to the sociology of knowledge is epitomized in three distinct claims. First, and most controversial, is the contention that boundaries between manifestly ideological and ostensibly scientific modes of explaining the cultural as well as the social world are porous, with sociology of knowledge emerging in the border region, as a reflexive therapy for both domains. Second is the concomitant conception of ideologies as cognitive structures that are variously flawed, limited, perspectivistically one-sided, subject to correction from other perspectives, and nevertheless productive of knowledge. The third claim, then, is that the sociology of knowledge bears on the answers to substantive questions addressed by ideologies, consequently contributing directly to political orientation. It does so not because knowledge of social genesis can determine judgments of validity, but because systematic pursuit of such knowledge fosters a comprehensive synthesis and renders particularistic ideologies obsolete.

Mannheim's strategy involves two steps. First, the variety of ideas in the modern world is classified according to a scheme of historical ideological types, in keeping with his thesis that the ideological field has moved from atomistic diversity and competition to concentration. Liberalism, conservatism, and socialism are the principal ideological types. Second, each ideology is interpreted as a function of some specific way of being in the social world, as defined by location within the historically changing patterns of class and generational stratification. Liberalism is thus referred to the capitalist bourgeoisie in general, and various stages in its development are linked to generational changes. Similar analyses connect conservatism to social classes harmed by the rise to power of the bourgeoisie, and socialism to the new industrial working class. Each of the ideologies is said to manifest a characteristic 'style' of thinking, a distinctive response to the issues that systematic philosophy has identified as constitutive of human consciousness, such as conceptions of time and space, the structure of reality, human agency, and knowledge itself. The political judgments and recommendations of purely ideological texts must be taken in that larger structural context. The style of thinking is most apparent in the way concepts are formed and in the logic by which they are interlinked. Each style expresses some distinctive design upon the world vitally bound up with the situation of one of the social strata present in the historical setting.

Sociology of knowledge seeks to give an account of the whole ideological field, in its historical interaction and change. To have a method for seeing this means to see in a unified way what ideologically oriented viewers can only see in part. Mannheim draws on Marxism for a conception of politics as a process of dialectical interplay among factors more 'real' than the competing opinions of liberal theory. But neither the proletariat nor any other socio-political force is bearer of a transcendent rationality, historically destined to reintegrate irrationalities in a higher, pacified order. The contesting social forces and their projects in the world are in need of a synthesis that incorporates elements of their diverse social wills and visions. Syntheses in political vision and in the social sciences are interdependent. Sociology of knowledge foreshadows and fosters both.

Mannheim's call to a professorship in Frankfurt followed the remarkable recognition earned by his further work in sociology of knowledge. In his presentation on *Competition as a Cultural Phenomenon* at the Sixth Conference of German Sociologists in 1928 (in Wolff, 1993), Mannheim audaciously used the value–judgment controversy in recent sociology to illustrate his theses about the connectedness of social thought to existence (*Seinsverbundenheit*) and the operations of socially grounded competition to generate syntheses that transcend intellectual conflict. *Ideologie und Utopie*, consisting of three essays on 'politics as a science,' 'utopian consciousness,' and an explication of the concepts of '*ideology*' and '*utopia*' generated great excitement that launched Mannheim in his new setting, recognized in the wider intellectual community as a significant and controversial personality. Questions about varieties of knowing and about the ways in which new knowledge depends on authentic grounding in the contexts of existing knowledge are the major themes of much of Mannheim's work during this period. His seminal paper on *The Problem of Generations* (1927), which continues to have a lasting impact in sociological research and analysis (especially by way of cohort analysis and the sociology of the life course), also belongs here.

The sociology of knowledge dispute about *Ideologie und Utopie* (Meja and Stehr, 1982, 1990) was primarily a philosophical and political dispute, with the focus, first, on Mannheim's hope of overcoming both ideology and political distrust by way of a sociology of knowledge; second, on his conception of the intelligentsia as the social stratum uniquely equipped and even destined for this task; and third, on his activist conception of sociological knowledge, as a mode of mediating between theory and practice. In *Science as a Vocation* (1922), Max Weber had distinguished between words in politics and in science, likening the former to weapons for overpowering opponents and the latter to ploughshares for cultivating knowledge. Mannheim offers the sociology of knowledge as an 'organon for politics as a science,' as a way of bringing about the biblical transformation of swords into pruning hooks prophesied by Isaiah. His proposals were widely canvassed in the leading periodical reviews and subjected to intense criticism, but his reading of the intellectual situation was almost universally applauded. In the cultivated Weimar public and among the participants in the 'Weimar conversation' about social thought after Nietzsche and Marx, *Ideologie und Utopie* figured as the representative book of its time, whether as symptom of cultural crisis or as promise of a way out. If *Ideology and Utopia* and *Structures of Thinking* represent Mannheim's most important theoretical exercises, his work on conservatism has commonly been taken as paradigmatic for an empirical sociological of knowledge.

During his five semesters as professor in Frankfurt (where Norbert Elias was his research assistant), however, Mannheim

declined the role of public intellectual. He deliberately separated the professional aspects of his activities from his public reputation. While drawing close to Paul Tillich and his circle of religious socialists, celebrated and embattled as an 'intellectual,' he nevertheless increasingly defined himself as a professional sociologist. Never having exposed himself politically, he was unprepared for the Nazi measures that deprived him of his professorship on grounds of his foreign birth and his Jewish ethnicity. *Ideologie und Utopie* had been favorably reviewed at length in the Socialist periodical, *Die Gesellschaft*, but the four articles published there (by Hannah Arendt, Herbert Marcuse, Hans Speier, and Paul Tillich), were all more critical than the reviews in *Die Tat*, a periodical of the activist Right. The hard Left treated him as a betrayer of Marxism. Soon Mannheim was a refugee in Amsterdam. Neither his sociology nor his politics had anything to do with his exile from Germany.

In the summer of 1933, Mannheim was appointed to a special lectureship at the London School of Economics. Neither the times nor his situation were conducive to pursuing sociology of knowledge studies, however. Mannheim saw it as his mission to diagnose the general crisis he held responsible for the German disaster and to promote prophylactic and therapeutic measures in Britain. His sense of urgency and his grand theoretical ambitions impressed students, but they estranged the professional sociologists led by Morris Ginsberg, who were engaged in a difficult fight for academic respectability of a discipline still widely dismissed by the English university establishment. Although marginalized at the London School of Economics, the only British institution with a chair in Sociology, Mannheim made a place for himself as a public intellectual, especially after his acceptance by a circle of Christian thinkers that included T.S. Eliot and whose periodic discussions and publications centered on a theme of cultural crisis hospitable to Mannheim's sociological interpretations.

In Britain, Mannheim continued to focus on the relationship between knowledge and society, his lifelong topic. Writing in *Man in Society in an Age of Reconstruction*, a work no less influential during the war and in the postwar years than *Ideology and Utopia*, he now claims that the sociology of knowledge has lost its strategic centrality with the demise of ideological competition (Mannheim, 1940) and calls for "a new experimental attitude in social affairs," in view of the "practical deterioration of the ideals of Liberalism, Communism, and Fascism." The National Socialist dictatorship, Mannheim argues, exploits a socially unconscious mass response to a worldwide crisis in the institutions of liberal civilization, involving the obsolescence of its regulative social technologies – from markets to parliaments to elitist humanistic education. He pleads for a planned social order that strategically utilizes the new social technologies that undermine the spontaneous self-ordering of the previous epoch. A consensual reconstruction could save human qualities and diversities earlier privileged by liberalism, unlike the violent homogenization imposed by communist or national socialist control through command. Timely action guided by awareness of the impending crisis by leading strata, notably the English elite of gentlemanly professionals, can tame the processes that would otherwise destroy liberal civilization and condition mass populations for dictatorial domination. 'Planning for freedom' presupposes a reorientation among traditional elites, their acceptance of a sociological diagnosis of the times, and their willingness to learn prophylactic and therapeutic techniques (Mannheim, 1943). Mannheim now claims for sociology the ability to ground and coordinate interdisciplinary approaches in planning. His lectures and writings on 'planning' won him an interested audience, especially during the war and immediate postwar years, and his conception of a postideological age was never altogether submerged by the Cold War (Mannheim, 1950). As his wartime slogan of 'militant democracy' justified German measures against leftists during the middle decades of the century, his slogan of the Third Way was heard at the beginning of the new millennium in support of political designs he would have found familiar.

Among sociologists, however, Mannheim's standing was defined by the reception of *Ideology and Utopia*. In his preface, Louis Wirth casts the work primarily as a contribution to objectivity in social science. The professional consensus is formalized in R.K. Merton's authoritative essay in 1945 on 'The Sociology of Knowledge' (in Merton, 1957). Merton includes Mannheim in a group of social theorists from Marx to Sorokin whose diverse approaches to 'the relations between knowledge and other existential factors in the society and culture' he relates to questions and alternatives that provide an agenda for the theoretical clarification and empirical research required to build sociology. Merton's 'paradigm' for the sociology of knowledge sets out five key issues: the existential basis of mental productions, the varieties and aspects of mental productions subject to sociological analysis, the specific relationship(s) between mental productions and existential basis, the functions of existentially conditioned mental productions, and the conditions under which the imputed relations obtain. Crediting him with having sketched the broad contours of the sociology of knowledge with skill and insight, Merton nevertheless finds Mannheim's theory burdened with dubious philosophical claims, and insists that the relations between knowledge and social structure can be clarified only after they are "shorn of their epistemological impedimenta, with their concepts modified by the lessons of further empirical inquiry" (Merton, 1957: p. 508).

The condition for Mannheim's acceptance as deserving sociological pioneer was the discarding of the concept of total ideology and his way of questioning both social science and social knowledge. The editors and organizers of three posthumous collections of Mannheim's essays, his close friends and noted social scientists, Paul Kecskemeti, Ernest Manheim, and Adolph Loewe, reinforced the consensus view. As Mannheim became acquainted with Anglo-American social science, they argued, empirical social psychology displaced continental philosophies as the theoretical framework for his thinking, and his early writings merit consideration primarily as brilliant anticipations of later developments. In Merton's sociological theory classes at Columbia University during the 1950s, *Ideology and Utopia* often followed Machiavelli's *Prince* in the syllabus, as source material for an exercise in transmuting suggestive ideas into testable propositions. Mannheim's work had joined the list of historical authorities

celebrated as legitimating precursors of a settled way of defining and doing sociology.

We can trace the renewal of attention to the historical social thinker, Karl Mannheim, to renewed conflicts about the subject, method, and attitude of sociology. The connection is not simple, since the attack on the disciplinary consensus, where historical models were involved, was more likely to call on Marxist writers or on figures like Theodor W. Adorno, Max Horkheimer, and Herbert Marcuse, who had been among Mannheim's harshest contemporary critics. The effect, nevertheless, was to relegitimate questions about the historicity of social knowledge, the problem of relativism, and the paths of reflexivity open to social thinkers – the issues filtered out of Mannheim's thought in his American reception – and to provide a new point of connection for those sociologists (e.g., Wolff, 1993) who had continued puzzling over the issues debated when *Ideologie und Utopie* first appeared. Berger and Luckmann's influential phenomenological reformulation of the sociology of knowledge in *The Social Construction of Reality* (1966) represents a departure from Mannheim's sociology of knowledge. All knowledge, both objective and subjective (and including ideology, propaganda, science, and art), is now seen as socially constructed. Berger and Luckmann examine how forms of knowledge are maintained and modified by the institutions and individuals embodying and embracing them.

In the newly fluid state of questions appropriate for sociological theory, Mannheim's famous *Ideology and Utopia* no longer stands alone among his writings, and his insistence on essayistic experimentalism is no longer ignored. There are no propositions to be distilled out of Mannheim's work; there is just the thoughtful encounter with it. Mannheim's prediction about the consequences of uncovering the 'massive fact' of knowledge in society and society in knowledge has been borne out. Today 'knowledge society' is a widely recognized and accepted concept. Yet we are not beneficiaries of any 'progress' in thought, as post-modernists paradoxically often suppose: we may well have to think deeply about old texts, however we class them.

Manual Based Treatments

Johanna Thompson-Hollands and David H Barlow, Boston University, Boston, MA, USA

Abstract

Treatment manuals were first developed in the 1950s and quickly became an important tool, allowing for the objective and replicable definition of a given psychological approach. Manuals greatly enhanced the rigor of treatment research studies, and they also provided an effective way to communicate treatment strategies to clients and clinicians at large. There are now dozens of manuals available, representing a range of problem areas and theoretical approaches. Although manuals have many advantages when compared to unstructured treatments, they have faced criticism from some practitioners. Nevertheless, manuals will continue to play an important role in psychological treatment in the future.

Introduction

The practice of psychotherapy has seen dramatic and sweeping changes since the 1950s. One of the most dramatic changes impacting the delivery and dissemination of specific psychotherapeutic service has been the development of detailed explanatory manuals for complex psychological treatments. In addition to manuals intended for use by therapists, client 'workbooks' are also available for use in therapist-directed treatment or as self-help resources. The main function of these treatment manuals is to provide an operational definition of a given psychotherapeutic approach, including acceptable procedures, techniques, and strategies (Chambless and Ollendick, 2001) and to make the process of psychotherapy more accessible to clients and clinicians alike. Typically, these manuals describe session-by-session strategies for specific problems such as depression or phobias for therapists to follow.

Many changes in the field led to the impetus for specific treatment manuals to be developed including the demand for 'good and better research,' in which the therapeutic intervention is specified for all to examine, and the burgeoning of the hegemonic managed behavioral health care system. In response to these many demands, the number of manuals has proliferated. Although the psychotherapeutic community has positively received the majority of manuals, some frontline clinicians raise objections to this approach, stating, among other objections, that manuals damage the therapeutic relationship, and that clinical innovation is restricted (Addis and Krasnow, 2000). Despite these obstacles, treatment manuals are now a well-established part of the dissemination and treatment landscape in clinical psychology.

Developmental History of Treatment Manuals

The initial impetus for the development of treatment manuals came from psychotherapy researchers who in the early 1960s began to test broadly the effectiveness of specific treatments in controlled outcome studies. At that time, psychotherapy outcome studies were methodologically crude, consisting largely of collections of case studies in which successful outcomes were attributed to the relevant 'school' of psychotherapy rather than to specific elements of treatment that could be examined individually (Barlow et al., 2013). The treatments administered in these studies were quite loosely defined, preventing the analysis of particular treatment components. Naturalistic studies were also conducted, incorporating many theory-driven measures of clinician and patient behaviors; such studies tended to utilize broad, heterogeneous groups of patients, and treatment decisions (use of medications, assignment of patients to particular therapists) were based on clinical judgment. Such designs produced results that were generally conflicting and of little scholarly value (May, 1973). Despite the lamentable state of outcome research during this time, a few prescient researchers recognized the need to pursue methods that could more closely tie process to outcome (Paul, 1967; Strupp, 1964).

Looking to demonstrate successfully that psychological interventions could withstand rigorous scientific investigation, similar to that of existing pharmacological treatments (Luborsky and DeRubeis, 1984), scientist-practitioners realized that they needed treatment tools that would allow for systematic replication and comparison. Psychotherapeutic procedures needed to be clearly specified in order to be tested accurately (Luborsky et al., 1975). As Bergin and Strupp (1972) noted, "In short, the therapist and the researcher must become increasingly *explicit about the operations of psychotherapy and the nature of the therapist's influence*. Existing knowledge, while undoubtedly embodying important psychological principles, is altogether too general, broadly-gauged, and imprecise …. [F]uture research in this area must rest firmly on empirical data; it must tend toward increasing explicitness and specificity; and it must seek to isolate psychological principles embedded in, and often obscured by, divergent theoretical formulations" (p. 436).

The creation of treatment manuals paved the way for a true science of treatment to emerge, for researchers were now able to outline a precise template of interventions that could be replicated with fidelity (Perepletchikova et al., 2007). Wilson (1996) more specifically pointed out that treatment manuals sought to eliminate any 'error' associated with 'clinical judgment' or intuition that might cause one therapist to behave in a substantially different manner from another. Many researchers hoped that by utilizing treatment manuals, presented in this fashion, psychological interventions would

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21045-3

be able to withstand the methodological constraints of research protocols. This provided a striking contrast to the conduct of treatment outcome research prior to manualization, in which specific therapeutic techniques were often not explained and thus could not be compared to other treatments or be replicated by other investigative groups. As a consequence, federal agencies in countries such as the United States and the United Kingdom began to request that investigators specify the use of a treatment manual in their studies when applying for funding.

System-Wide Adoption of Manualized Treatment

While early manuals were usually developed in order to facilitate and strengthen research, manuals are now the primary mechanism for dissemination of empirically supported psychological treatments. In recent years, national-level programs to support the use of manualized, evidence-based interventions to treat mental illness have been established, with governments committing billions of dollars to the cause (McHugh and Barlow, 2010). In the United States, the Veterans Health Administration (VHA) produced a new Mental Health Strategic plan in 2004, including goals for disseminating evidence-based psychological treatments into practice throughout the VHA system. Several manual-based treatments for specific disorders relevant to a veteran population, including cognitive-processing therapy (CPT; Resick et al., 2007) and prolonged exposure (PE; Foa et al., 2007) for posttraumatic stress disorder, were 'rolled out' system-wide (Karlin et al., 2010). Phase I of this roll-out process for CPT and PE involved the development of treatment manuals tailored to a veteran population. All VHA mental health clinics are required to have staff members who are adequately trained in the interventions, and the explicit goal of the program is to have such treatments become the standard of care (McHugh and Barlow, 2010). In the United Kingdom, a similar program, Improving Access to Psychological Therapies (IAPT), was announced in 2007 (Clark et al., 2009); the initiative is extensive, with rigorous standards for training in and implementation of the supported treatments. The IAPT represents the single largest commitment of a national agency to dissemination of evidence-based psychological treatments thus far, and initial results have indicated that the program's goals of increasing referrals and access to empirically supported treatments are being met (Clark et al., 2009).

Across these large-scale initiatives, clinical practice guidelines and quality standards explicitly articulate the optimal strategies for assessing and treating a variety of psychological problems. Treatments recommended in Psychotherapy Clinical Practice Guidelines are typically based on two specific factors: (1) efficacy, or internal validity of the specific treatment, the determination of which is based on the results of a systematic evaluation of the intervention in a controlled setting, and (2) effectiveness, or clinical utility of the treatment, which is based on the feasibility, generalizability, and cost-effectiveness of the intervention actually being delivered in a local setting. Based on these equally important and rigorous principles, the use of treatment manuals that can produce the necessary evidence is encouraged (Chambless and Ollendick, 2001). Strosahl (1998) points out that manuals are especially appealing to managed-care settings because they are essentially an easily discernible road map for the most appropriate way to implement clinical practice guidelines. Within managed care organizations, where psychotherapy (1) must demonstrate its overall effectiveness, (2) may be limited to a certain number of sessions, and (3) increasingly is delivered by practitioners with less than doctoral degrees, treatment manuals are embraced for their ability to facilitate the delivery of empirically supported treatments at lower costs. As a result, manual-based treatments have been incorporated as one of the major components of evidence-based service delivery (Roth and Pilling, 2007).

Specific Treatment Manuals

The majority of current treatment manuals are based on behavioral techniques rather than more traditional psychotherapy models, which tend to emphasize a more individualized theory-based understanding of underlying patient problems (Wilson, 1996). Currently, specific manuals exist for many diagnostic categories specified by Diagnostic and Statistical Manual of Mental Disorders, 4th edition, including a wide variety of anxiety disorders such as panic disorder, generalized anxiety disorder, obsessive-compulsive disorder, posttraumatic stress disorder, and social anxiety disorder. Most of these manuals utilize cognitive and behavioral therapy (CBT) techniques with an emphasis on identifying and challenging maladaptive cognitions and eliminating behaviors that serve to increase and maintain anxiety (e.g., Barlow et al., 2011; Craske and Barlow, 2006; Foa et al., 2012). Other manuals with a cognitive behavioral emphasis include treatments for bulimia nervosa, weight reduction, stress reduction, depression, addictive behaviors, and sexual dysfunction (e.g., Antoni et al., 2007; Apple and Agras, 2007; Daley and Marlatt, 2006; Gilson et al., 2009). Newer approaches to cognitive-behavioral techniques that incorporate mindfulness and non-judgment in addition to some of the more traditional CBT elements have also been written into manuals for a variety of problem areas (e.g., Forsyth and Eifert, 2008; Woods and Twohig, 2008).

Although cognitive behavioral manuals tend to predominate, other forms of therapy have also followed this route as the benefits of manualization (ease of dissemination and training and replicability across research studies) have become more recognized. Family-systems approaches for disorders ranging from bipolar disorder and schizophrenia to eating disorders have been published (e.g., Lock et al., 2012; Miklowitz, 2010). Manuals also exist for social skills training, problem-solving therapy, and supportive/expressive therapies, among others (e.g., Bellack et al., 2004; Nezu et al., 2012; O'Connor and Ammen, 2012).

Pros and Cons of Treatment Manuals

One distinct advantage of treatment manuals is that they have been shown to be effective in controlled treatment outcome studies (Barlow, 2004; Nathan and Gorman, 2007). Thus,

when practitioners implement techniques, they can do so with the confidence that they are delivering services that have a high probability of success. Furthermore, manuals guide clinicians to use strategies that are spelled out and are clearly discernable. This allows for the examination of treatment integrity, including therapists' treatment adherence and competence, as well as differentiation from other treatment approaches (Perepletchikova et al., 2007). As mentioned above, poor treatment integrity compromises the validity of research findings and hinders replication attempts. By providing a specific outline of techniques, manuals impose structure upon the therapist and communicate discrete parameters regarding the treatment itself.

Wilson (1996) points out that treatment manuals can reduce the errors that might be associated with unrestrained clinical judgment. "What is typically overlooked, however, and what research on human judgment so clearly documents, is that individualized clinical judgment can just as easily produce worse results than standardized treatments, by introducing errors and inappropriate strategies that are not part of manual-based treatments" (Wilson, 1996, p. 302). Manuals, however, outline specific techniques to be used in each session, which have been created by systematic investigation, rather than relying upon clinical judgment to choose a session topic.

Due to their structure, treatment manuals may also facilitate a more highly focused and efficient therapy. With a limited number of sessions and specific goals and strategies outlined for each of these sessions, this more focused approach may actually lead to a more active engagement in therapy for patients and encourage efficiency on the part of clinicians.

Treatment manuals also make it easier to train and supervise therapists in specific clinical techniques and strategies (Calhoun et al., 1998). By providing nascent clinicians and supervisors with specific guidelines and techniques to monitor, treatment manuals streamline the learning process and delineate a specific set of therapeutic skills to be learned. This in turn may lead to a greater aptitude and ability for learning therapeutic techniques in general, and a larger armamentarium of clinical skills.

Treatment manuals, as structured interventions, can also help clinicians deliver therapy in a brief and in many cases nontraditional format (Craske et al., 1995). For example, a manualized version of brief problem-solving therapy for depression was administered by both primary care physicians and by nurses; patients' improvement was not significantly different whether a physician or a nurse treated them. Additionally, the therapy-alone conditions were not significantly different from either a medication alone condition or a combined treatment condition (Mynors-Wallis et al., 2000). Considering the high prevalence rates of clinical and subclinical mental disorders in primary care settings (Kroenke et al., 2007), such interventions are clearly cost-effective.

Despite these many advantages, a sizable segment of practicing clinicians object to the notion of treatment manuals, pointing out the many disadvantages in the delivery of what has been called derisively, robotlike therapy (Addis and Krasnow, 2000). For example, dissenters have argued that randomized controlled trials, utilized to validate most manualized treatments, exclude patients with comorbid diagnoses, among other constraints, and that the results of these types of research studies, including the treatments they produce, inherently have limited applicability to 'real-world' settings (Bologna et al., 1998; Carroll and Nuro, 2002). These same individuals note that highly structured, manualized psychological interventions used in clinical trials cannot generalize to practice settings where psychotherapy is often applied more flexibly and adapted to meet the needs of the patients, who may present with multiple problems (Barlow, 1996; Jensen-Doss et al., 2009; Nelson et al., 2006). This set of objections is based on the fundamental idea that the scientific method, as it is known, is incapable of proving the effectiveness or ineffectiveness of psychotherapy, and that some alternative methodological approach to psychotherapy research is preferable. These are important criticisms that cannot be ignored. However, manualized treatment need not be delivered rigidly; even though the therapist utilizing a treatment manual is delivering a particular set of outlined techniques, within this delivery they are also encouraged to rely on their own personal skills to convey the therapy to the patient (Kendall et al., 1998). For example, clinicians in the Treatment of Depression Collaborative Research Program were adherent to the study's treatment manual while also flexibly adapting their presentation and interaction style as appropriate to a particular patient (Gibbons et al., 2002). Importantly, research has also shown that the overall amount of therapist flexibility does not predict patient outcomes (Kendall and Chu, 2000), suggesting that the importance of tailoring interventions to a given individual may be overstated. Mounting evidence suggests a high degree of generalizability of manualized treatments to front-line clinical settings despite substantial comorbidity and a diverse population base (Barlow et al., 1999).

Other clinicians bemoan that structured treatment manuals will compromise the integrity of the therapeutic relationship and thus interfere with the therapy process (Addis et al., 1999). For example, many of these clinicians fear that manualized therapy may reduce the therapy process to mechanized and robotic delivery of techniques, thereby eliminating the importance of the therapist as a clinical tool. However, Wilson (1996) notes, "if clinical artistry is taken to connote such necessary therapeutic elements as developing a therapeutic relationship and engaging patients in the change process, then treatment manuals do not obfuscate it – rather they demand it" (p. 305). The data indicate that therapists engaged in manualized treatments in clinical practice can form strong alliances (Addis, 1997; Creed and Kendall, 2005). Simply because the therapist has to spend a segment of time conveying specific therapeutic techniques does not mean that they are not building alliances with their patients. Furthermore, a great deal of time is allotted in manual-based therapies to emphasize relationship building and exploring the patient's unique perspective. Examples include such strategies as identifying client and therapist expectations for treatment, eliciting client feedback, and exploring motivation for change (Barlow et al., 2011; Hope et al., 2010).

Criticisms of treatment manuals also encompass the belief that manuals may undermine successful case formulation. That is, many clinicians argue that manual-based treatments will be less effective because these approaches assume that all

individuals with a given disorder are uniform and have the same symptoms for the same reasons (Wilson, 1996). As such, these techniques will 'miss the boat' for a certain subset of patients and will attempt to treat them with techniques that are not applicable. The fact that manuals do not allow for clinical exploration that might lead to the discovery of what works for patients with dissimilar etiology is a commonly expressed concern that may lead to diminished treatment innovation. In fact, treatment manuals do emphasize the current symptom picture over past development processes and idiosyncratic etiology. But research has yet to suggest that therapeutic attention to past developmental processes contributes in a substantial way to the amelioration of the disorder.

Finally, utilization of treatment manuals can promote innovation in the delivery of clinical services. That is, when highly specified treatments are delivered, and assuming appropriate outcome measures are collected, clinicians can determine when a specific treatment is working and for whom. In the case of failures, either individually or systematically, it will then be clear that innovations to the treatment program are needed and should be incorporated and evaluated. If data are systematically collected regarding who responds to the treatment and who does not, along with responses to second-stage interventions, innovations in treatment will occur much more rapidly than with unstructured approaches.

Many of the criticisms of manualized treatment have some validity, and researchers continue to explore issues relating to the acceptability and external validity of manual-based treatments. However, a large subset of practicing clinicians continues to report no or low levels of familiarity with these protocols (McHugh and Barlow, 2012); moving forward, it is critical that evaluations of manualized treatments be based upon their true performance, rather than on worst fears of their potential shortfalls.

The Future of Structured Treatment Manuals

The move toward treatment manuals has radically shifted the science and practice of psychotherapy over the last half century. Despite some objections and lingering doubts, treatment manuals have many merits, with demonstrated efficacy the principal attribute, and will clearly continue to shape the treatment of mental illnesses for years to come. As one looks ahead to the future of these evidence-based psychological interventions, challenges have become apparent. The first challenge is making these treatments more available to the people who would benefit from them. Given the difficulty of successfully disseminating and implementing even one evidence-based treatment into routine practice (McHugh and Barlow, 2010, 2012), it has become apparent that large-scale dissemination of treatments focused on single psychological disorders is not feasible. One more parsimonious alternative, transdiagnostic treatment protocols, can provide a comprehensive, theory-based approach to addressing a range of diagnoses and comorbidities. This reduces training burden for clinicians while maintaining the advantages of manual-based treatment. A second challenge relates to moving treatment 'beyond the book' using stepped care models and a variety of delivery methods. The need for mental health services vastly outpaces the available number of clinicians, creating a need for creativity in the administration of treatment (Kazdin and Blase, 2011; Kazdin and Rabbitt, 2013). Stepped care approaches provide several levels of treatment depending on the needs of the individual patient. Many individuals may be able to benefit from lower intensity interventions that do not require a highly trained mental health professional, such as guided self-help; treatment manuals are ideal for this format. The books may be used on their own, or the treatment protocol may be integrated into an interactive computer or web-based program with features such as video clips and regular progress assessments. These approaches increase the availability of high-quality treatment services while also reducing cost and system burden.

Māori Social Work

Abstract

In Aotearoa/New Zealand, the term 'Māori Social Work' emerged from a bicultural approach to the delivery of social services. This term has gained recognition in academic forums and the community as Māori and non-Māori authors attempt to provide descriptions and definitions to deconstruct the meaning. Māori Social Work can be located in the Western worldview and the Māori worldview. Within these worldviews the term weaves together theory and practice. It represents formal and informal types of social service delivery and is embedded in the philosophies of matauranga Māori (Māori knowledge and Māori education). Māori Social Work is broad, holistic, and grounded in tikanga (customs) and reo (language).

Introduction

Māori Social Work is communal social work. Māori people have always exercised aroha (compassion, love, help, and support), awhi (helping people), kaitiakitanga (guardianship), mahi (work), manaakitanga (caring for people, living things, heaven, and earth), tautoko (support for another), and whakawhanaungatanga (relationships, getting to know each other, and building relationships). For Māori, these exercises are the foundations of communal life in Te Ao Māori (Māori world). Māori, the native aboriginal and Indigenous ethnicity to Aotearoa/New Zealand (Aotearoa), signed the Treaty of Waitangi (Treaty) with the British Crown in 1840. The term Māori did not exist, instead chiefs from hapū, the Indigenous name for clans, signed the Treaty with representatives of Queen Victoria from Britain. When these two different ethnicities, Māori and European (Pākēhā), signed the Treaty, this contract gave birth to a bicultural nation. Māori culture thrived and they represented the majority population, but the British dishonored their part of the Treaty. Britain colonized Aotearoa through legislation, education, religion, diseases, and force to overthrow and subjugate Māori people and assume power.

From the colonization of Aotearoa, a bicultural view of the world developed. These were the Eurocentric colonial world, referred to as the Western world, and the world of the native aboriginal that was colonized, the Māori world. Subsequently, the two worldviews coexisted for over a century. Understanding the Māori worldview broadens a person's knowledge of Indigenous social work. A century later, the importance of the Māori people and the Treaty became recognized in bicultural social work practices in Aotearoa. This article explains Māori Social Work through a Māori lens and discusses the impact from Western worldviews to Māori knowledge, practice, and the delivery of social services that shaped Māori Social Work.

Western Worldview

Western worldviews of social work dominate the literature. The International Federation of Social Work (IFSW) and the International Association of Schools of Social Work say social work is a profession and an academic discipline. This Western worldview defines social work as promoting.

> social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being. Utilising theories of human behaviour and social systems, social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work.
>
> (IFSW, 2012, p. 1)

The definitions provided a singular view and neglected an Indigenous worldview of social work giving Western views power over Indigenous ones. The inclusive and supportive language used in this definition fashions knowledge to be homogeneous and portrays a universal worldview of social work. Sewpaul and Jones (2004) argue that the definition does not purport to provide a universal worldview:

> The extent to which schools of social work meet the global standards will depend on the developmental needs of any given country/region and the developmental status of the profession in any given country, as determined by unique historical, sociopolitical, economic, and cultural context.
>
> (Sewpaul and Jones, 2004, p. 226)

In a country where Indigenous people have been colonized, the definition is accepted by the majority as the indicator for measuring quality standards attached to social workers and social work despite local reality being different. The approach to dominate the discourse can be considered colonization by words applied in a subtle manner. It can be reinforced through legislation, government policies, academic success, rules, and regulations. This reinforcement can be seen in the Social Workers Registration Act 2003 and supported by the Social Workers Registration Board that "maintains a focus on the introduction of mandatory registration, which was one of the principal recommendations resulting from their 2011/12 review of the Act" (New Zealand Parliament, 2013, p. 3).

Traditionally, social work for Māori did not exist, instead Māori exercised values such as manaaki (to care for), aroha, kaitiakitanga, and rangatiratanga (leadership) when working

with tangata (people). In the last decades, the notion of Māori Social Work has emerged and values such as manaaki, aroha, kaitiakitanga, and rangatiratanga have reflected the common interpretations of social work that Māori exercised mainly as volunteers. "For many Māori, voluntary activity (acts of service to the people of the whānau, hapū and Iwi) was seen as an expression of the Māori philosophical cornerstones of collective consciousness, collective wellbeing, and collective responsibility" (Gray, 2002, p. 41). Gray (2002) stipulated that notions of 'voluntary work' had no traditional equivalent and providing services to people were an overarching philosophy in Māori families that entwined the values of voluntary work and social work. This is shown in the results of a research on voluntary activity by the New Zealand Office for the Community and Voluntary Sector.

> Māori were more likely than non-Māori to have been involved in unpaid activities outside the household….The fact that Māori women undertake more unpaid work outside the home than Māori men has been attributed to particular gendered roles that are ascribed to women on the marae.
>
> (Office for the Community and Voluntary Sector, 2007, p. 3)

Professional social work, according to Aotearoa NZ Association of Social Work (ANZASW) (2008, p. 2), "is focused on problem solving and change. As such, social workers are change agents in society and in the lives of the individuals, families and communities they serve." Kuther (2013, p. 1) describes a professional social worker as a person that helps "manage their daily lives, understand and adapt to illness, disability, and death, and obtain social services, such as health care, government assistance, and legal aid." Helping people can be a challenging task if the worldview one sees is not Western. Hart (2010) identifies this challenge and concurs that

> in any society there is a dominant worldview that is held by most members of that society…Alternative worldviews do exist, but they are not usually held by a majority of a society….work with Indigenous peoples will often require us to act outside of the dominant worldview found in social work internationally and particularly in fourth world territories.
>
> (Hart, 2010, p. 2)

A research report, *Puao-te-Ata-Tu*, produced results that government agents working in the Department of Social Welfare were racist and the quality of service to Māori was poor (Ministerial Advisory Committee on a Māori Perspective for the Department of Social Welfare, 1986). The research prompted a Minister of Parliament to review the Department of Social Welfare and adopt the notion of involving whānau when working with an individual client. The Children, Young Persons and Their Families (CYPF) Act 1989 was introduced that led to the creation of the Family Group Conference (FGC). "Social workers responded to the challenges of *Puao-te-Ata-tu* by developing practices that encouraged a greater degree of family/whānau involvement both in decision-making and with respect to hapū and extended family kinship care" (Connelly, 2004, p. 2).

FGC is a meeting between a young person who has offended his/her whānau, victims, and other people. The other people can represent various professionals like the police, counselor, a social worker, or youth advocate, who contribute to discussions with the whānau, victim, and youth. The formal meeting is organized by government agents with three main stages. Stage one is time for the professionals to inform whānau of their issues and concerns. In stage two, whānau are given time to discuss the information they have received and develop a plan to address the issues or concerns. In stage three, the plan is presented to the professionals, victims, and others and modified to suit the situation with feedback/contributions by all those involved (Child, Youth and Family, 2013).

Understanding Indigenous worldviews, Hart (2010, p. 1) argues, is important for the development of social work theory and social work practice. Accordingly, "our worldviews affect our belief systems, decision making, assumptions, and modes of problem solving." From a Māori worldview, values and practices are grounded on matauranga and individuals are always part of a collective that share their problems in life. Individual confidentiality rights gave way to whānau rights meaning the social worker could share with whānau the social issues of the client. The use of the FGC process changed social work with Māori clients.

Academic institutions produce predominantly Western worldviews of social work. Dumbrill and Green (2008) discuss how these institutions have changed once they realized their oppressive impact upon Indigenous people from the delivery of educational content that failed to acknowledge the value of Indigenous knowledge. "Consequently, social work academies, particularly in Canada, the United States, Central and South America, as well as Australia and New Zealand, are attempting to include Indigenous knowledge in the curricula" (Dumbrill and Green, 2008, p. 490). They argue that academic institutions need to be

> sensitive to the ways [in which] European knowledge dominates the academy and [become] open to disrupting this domination. Disruption is crucial because, despite a commitment to diversity and inclusion, most social work academies continue to teach from a Eurocentric perspective in a manner that perpetuates the colonization of not only Indigenous people and knowledge, but all other peoples and knowledge that falls outside the dominant European paradigm.
>
> (Dumbrill and Green, 2008, p. 490)

Determining who is a social worker, from an Indigenous view, is not solely dictated by academic institutions or governments. Neither should professionals and registered social workers be the only experts of social work practice for Indigenous people. Dumbrill and Green (2008, p. 500) assert that academic qualifications like a doctorate do not signal an automatic ability to "understand or teach Indigenous knowledge nor does it signify the ability to evaluate student's learning in this area. Even those with PhDs based in feminist or post-modern epistemologies cannot be relied on to understand or teach Indigenous knowledge." They say the origin of these academic qualifications for Europeans can limit their understanding of Indigenous people, and suggest "for

Indigenous communities and thinkers, not European thinkers no matter how progressive they might be, to determine the Indigenous knowledge to be taught and the standards to be applied when evaluating this learning," placing control of Indigenous knowledge in Indigenous hands. Dumbrill and Green (2008, p. 500) explain that their position is not to deter Aboriginal scholars from being high achievers in academia, but to stipulate that "a PhD is not the only criteria within academia that should count towards who is recognized as a Professor with knowledge that has value." Subsequently, community experts that may not possess formal qualifications, or be considered as professionals, but acknowledged for their work with Indigenous communities, can enter this knowledge realm. Bell (2006, p. 16) shows how the discipline of social work for Māori can assist in bridging many communities. She says "if a facilitated process of decolonisation has a role to play in healing the effects of colonisation amongst Māori and other indigenous peoples, then social work could be a context in which this facilitated process of decolonisation could be accessed."

Māori Worldview

The Māori worldview locates knowledge in Māori tikanga and reo. Maintaining Māori tikanga and reo in social work is a complex undertaking because it requires many attempts, to compete against, change or challenge, the mindset of people that hold fast to the Western worldview. Pohatu (2003, p. 2) says, "the ability and willingness to construct, apply and defend Māori Social Work options" can be scary and exciting with liberating possibilities. He uses a Māori proverb to explain his intellectual position.

> Māori world-views it is proposed here, demonstrate the 'ka hao te rangatahi' angle of the whakatauki (valued and wise cultural sayings)…in this context is Te Ao Māori (Māori thinking and its world-views) and what it offers social work theory and practice, especially in Aotearoa.…in its dialectical role, is consequently interpreted here as recognising the limitations that exist within current social work theory, practice and so their educational learning pathways. The need to respond proactively to the social work reality within Aotearoa is the constant companion in this dialogue.
> (Pohatu, 2003, p. 1)

Pohatu (2003) shows how language educates, informs, influences behavior, describes, and shapes the actions of people as a cultural norm. "Simple words used daily within social work environments, exemplify this force. The words, 'client' and 'customer' have their own bodies of knowledge and rationalizations" (Pohatu, 2003, p. 1) and relationships are connected to conduct, and the thought processes between those in need, and those who provide a service for them. He informs Māori people to look at their behavior, the language used, and the ethical implications of this work. Māori language, to him, is the kaitiaki (guardian) and the spoken word is an energy that permeates through a person with entry points to deeper readings because "Man cannot tune in so to speak when he is incapable of responding to the vibrations of the language" (Pohatu, 2003, p. 2). Ruwhiu (1999, p. 58) also speaks of how words are used in social services. He says the term Māori "is often used interchangeably with tangata whenua. What does this all mean for non-Māori social workers dealing with Māori clients? Simply, to be prepared to mediate in the mouth of the tiger." In addition, he adds, "the foundation stones of social work partnership, resistance, and activism for both Māori and non-Māori social workers have been refined on the raging fires of Te Tiriti o Waitangi" (Ruwhiu, 1999, p. 54), the Treaty of Waitangi.

Hollis-English (2012) illustrates how the knowledge from the writings of Pohatu (2003) explains Māori Social Work theory. Pohatu's use of the word 'Āta' is drawn out specifically to show the Māori theoretical position of social work. She does this to make it clear that nurturing and growing relationships are useful to a social worker. Hollis-English (2012, p. 47) communicates "social services as a transformative approach for Kaupapa Māori initiatives. It is about building and looking after relationships and can support practitioners with understanding relationships and wellbeing when interacting with Māori." She comments that Āta described by Pōhatu is a "behavioral and theoretical strategy for building and maintaining relationships. This principle is particularly relevant to the analysis of Māori social work practice and experiences as it helps to understand how these domains function and interconnect" (Hollis-English, 2012, p. 47).

Māori Social Work is not separated or divorced from the politics and public issues in Aotearoa. For example, a surge in social problems like domestic violence, criminal activity, and child abuse automatically leads to the media overemphasizing/sensationalizing Māori involvement in these activities (Merchant, 2010). This type of media coverage can spread negative interpretations of Māori causing the mainstream population to act inappropriately toward them. History gives numerous examples of this inappropriate behavior (Merchant, 2010). In turn, Māori become skeptical about professionals and disengage causing a breakdown of relationships with social workers.

Walsh-Tapiata (2008, p. 115) argues, "cultural legitimacy of Māori knowledge and values are being transposed into everyday practice." She is encouraged by Indigenous writers leading the transformation of social work practice. Institutions that teach social work, she considers, are "starting to see a trickle of students who come from such backgrounds, and an increasing number of Māori practitioners who have a strong cultural identity are effecting changes in practice across a range of the helping professions" (Walsh-Tapiata, 2008, p. 115). Māori social workers, according to Hollis (2006), identify with Te Ao Māori "and are guided by its worldview" (Hollis, 2006, p. 39), that is, closely associated with the Treaty of Waitangi. This relationship between social work practice and the Treaty of Waitangi is shared by Walsh-Mooney (2009, p. 69), who reinforces the notion that Māori social workers "are informed by a Māori worldview."

Māori Social Work

ANZASW Social Work Registration Board developed a bicultural policy in their Code of Ethics making it distinctive.

In 1993, the ANZASW set up a committee in Aotearoa that managed complaints from people and organizations, and established a Code of Ethics and a Bicultural Code of Practice. "The Bicultural Code of Practice continues to be incorporated in the ANZASW Code of Ethics in recognition of the Treaty relationship" (ANZASW, 2013, p. 2). This development "attempts to model an ideal treaty relationship. It does so, not only through being bilingually written, but also by developing core values, one of which is about ensuring members are committed" (Hollis-English, 2012, p. 40), and thereby making "social service legislation, structures, organisations and social work practice grounded in the Articles of Te Tiriti o Waitangi" (Aotearoa Association of Social Workers, 2008, p. 1). From an academic position, Māori professionalism in social work is promoted.

Professionalism and registrations influence Māori Social Work. Walsh-Tapiata (2008, p. 114) considers that the Social Work Registration Act (2003) presents "a new set of issues for Māori social workers, many of whom have worked much of their lives in their communities but who may not have a recognized social work qualification." Māori social workers enroll in courses offered by academic institutions that are designed to meet the requirements of the Act. This enrollment challenges the values of voluntary work and social obligations that Māori community workers predominantly undertake without being educated or registered. The government funds a range of social service organizations like Charitable Trust, Incorporated Societies, Māori organizations, and Iwi organizations to deliver social services to Māori. "Māori organizations can become established under the Māori Trust Boards Act, the Māori Community Development Act and Te Ture Whenua Act, which differentiates them from the realm of incorporated societies and charitable trusts" (Hollis-English, 2012, p. 69). Eligibility for funding can influence the functions of a Māori organization to deliver social work.

The insertion of Māori Social Work values must be heralded when placed within legislation, models of practice, and standards of competency for social workers "to practice with Māori clients. This legislation has increased the number of Māori social workers becoming members of the Aotearoa Association of Social Work (ANZASW)" (Walsh-Tapiata, 2008, p. 114). Subsequently, the Tangata Whenua Social Workers Association as a separate body to ANZASW was formed and established a platform to discuss Indigenous issues relating to social work. This Association provided a Māori worldview of the social work profession.

> Rangatiratanga has always been the aspiration of New Zealand's indigenous social workers. The development of 'by Māori for Māori' services has grown progressively over the past twenty years. Māori practice models, Māori frameworks, Māori fields of practice and Iwi/Māori social services are all assertions of rangatiratanga. An Association of Social Workers that commits to support Māori practitioners is a natural progression of the aspiration.
>
> (Tangata Whenua Social Workers Association, 2013, p. 1)

The vision of tangata whenua practitioners to provide advice that is adopted in social work policy became an accomplished dream. "The need to develop an ethical framework, practice standards, competencies and professional development opportunities that acknowledge mohiotanga (knowledge), matauranga (education), maramatanga (understanding), matatautanga (proficiency and fluency) and marautanga (curriculum and syllabus) provided the impetus for the establishment of the Tangata Whenua Social Workers Association" (Tangata Whenua Social Workers Association, 2013, p. 1).

Legislation can impact negatively on Māori Social Work. This is seen in the policies, rules, and regulations regarding the care of children for families of Māori ethnicity. Barret and Connolly-Stone (1998) critically analyze the CYPF Act 1989. They highlight the hypocrisy of the legislation with regard to the Treaty because it mentions "the special needs of Māori, but avoids creating Treaty obligations for Government by not mentioning the Treaty" (Barret and Connolly-Stone, 1998, p. 40).

> The CYPF Act requires that families and Whānau, Hapū, Iwi and family groups be involved in deciding the best ways for addressing care and protection needs or dealing with offending behaviour. It is the first legislation that defines family as any person who has a kinship relationship to a child or young person or any person with whom the child or young person has formed a significant bond. In the case of Māori children and young persons, the Act recognises that family groups can include all members of a Hapū or Iwi.
>
> (Department of Social Welfare, 1997, p. 1)

In 2003, a Chief Executive Officer (CEO) of an Iwi social service agency was interviewed by the Ministry of Justice. The commentary showed a lack of skilled professionals who understand matauranga Māori and the impact of legislation on Māori Social Work. Without this skilled comprehension, social work professionals are limited to the services they can provide Māori.

> The philosophy of the CEO, and the philosophical base of the organisation are clearly grounded in the Maori worldview described in the literature search. Whakapapa is the basis for Whānau engaging with the Iwi Social Service, and children who whakapapa to this Iwi are seen as belonging to the Whānau, Hapū and Iwi. Whānau, Hapū and Iwi are responsible for the care of the children. A fundamental concern for Iwi Social Service providers is that these principles, which are referred to in the Children, Young Persons, and Their Families Act 1989, are incorporated into other Family Court law. Consistency at this level should be supported by trained professionals and these principles applied in an informed way.

Understanding Māori Social Work involves entering a new realm for many social workers. Pohatu (2003), Walsh-Tapiata (2008), Walsh-Mooney (2009), and Hollis-English (2012) identify mātauranga Māori as common words associated to Māori Social Work. Mātauranga Māori is a broad concept that covers tangible and intangible knowledge and cannot be compartmentalized into a basic definition. Rather, in the social work discipline it expands to describe the spirit and soul of the social worker and client. "This includes tikanga practices that Māori social workers have developed and applied to social work situations for the benefit of Whānau

Māori" (Hollis-English, 2012, pp. 16, 17). Hollis-English makes direct references to Māori Social Work to suggest, "knowledge that has come out of Te Ao Māori, the various contemporary methods and models that have been developed, and the ability to adapt these to the various Māori families with Aotearoa/New Zealand" (Hollis-English, 2012, p. 17).

Whakawhanaungatanga is entrenched in Māori Social Work. "For Māori families it is necessary to work collaboratively with tribal and Māori organizations who often have the insider networks and practices necessary to work effectively with their own people" (Walsh-Tapiata, 2008, p.112). Social workers can find certain behavior unacceptable, like a Māori client agreeing to everything suggested and entering agreements without understanding the punishment incurred from failure to comply. Whakawhanaungatanga can deter this behavior and enable the social worker and client(s) to get to know each other to generate positive results. When social workers work collaboratively with tribal and Māori organizations, the outcomes of success for the Māori clients are greater. Whakawhanaungatanga can assist in the prevention of an offense, a lessening of fear, and the fashioning of an agreement that the whānau and social workers are more likely to achieve. In Māori Social Work, whānau and the client are entwined and not viewed as independent of each other. Rather, the client is the whānau, and the whānau is the client as all members of the family are affected, one way or another, with the concern at hand that has brought the social worker(s) in front of them.

Māori Social Work embraces mahi aroha (working for compassion and love). This notion, mahi aroha, is strong in the community and can be delivered by professionals in paid positions or volunteers who are unpaid. Hollis-English (2012, p. 69) says, "government changes such as the employment of Māori staff and the CYPF Act were also affecting NGOs, Māori had different views of accountability and what volunteering entailed." In addition, Māori operated social services within the Māori organizations from whānau, hapū, and Marae (tribal meeting place). These organizations are less formal, very active in the community, and hold more autonomy over the delivery of social services. In the Māori world, "the underlying motivation to participate in unpaid work was the knowledge that to work the land that fed and housed the Whānau required unpaid labor. This knowledge spiritually bonded the members to the concepts of reciprocity and mutual responsibility" (Te Momo, 2003, p. 3). Tennant (2001) stipulates, when Indigenous voices began to be heard, the contribution by Māori voluntary organizations to the delivery of social services became noticed. As a consequence, government recognized the capacity of these organizations and a "shift in resources to Iwi and Māori-run services grew, in part, from a sense of historical injustice. In this context, Māori groups are not simply competitors for government support, but Treaty partners" (Tennant, 2001, p. 157).

Whānau are imperative to the health and well-being of social work clients. Hollis-English (2012, p. 196) purports, "Whānau as a collective group is/are instrumental in shaping Māori Social Work development and the lives of Māori social workers and second that it is a key priority area of Māori that work in the social work field." Adding to this field of social service delivery was Te Momo's (2003) earlier writings on Māori volunteerism:

> For Māori, participating in voluntary associations strengthened the new types of Māori communities and provided a way to address social problems by taking on the responsibilities to care for families. However, the vehicle for this early strength, the integration of Pakeha values and ways of working may also be seen to have contributed to the undermining of Māori ways of doing things that manifested Māori identity and values through Māori ways of working.
> (Te Momo, 2003, p. 6)

Whānau Ora, family well-being, is a founding principle that has underpinned Māori Social Work. Māori philosophers and practitioners like Sir Mason Durie, and Māori members of parliament, for example, the Honorable Tariana Turia, battled to create a policy named Whānau Ora. This policy impacted directly on social service organizations that accessed funding to deliver a social service to Māori and non-Māori. Research was initiated to "bring together government, providers and whānau, as the model provides for whānau having the opportunity to participate and voice their expectations from service delivery; and providers supported to design and deliver quality holistic services to whānau" (Turia, 2010, p. 4). Te Puni Kōkiri (2011, p. 1) comments that Whānau Ora, launched in 2010, was "an inclusive approach to providing services and opportunities to families across New Zealand. It aims to empower families as a whole, rather than focusing separately on individual family members and their problems." From 350 providers, a group of 25 was selected to deliver the services.

Māori Social Work resides in Māori development. Durie (2003) interprets Māori development to be holistic and have three core areas of development: social, political, and economic. Throughout extensive investigation of Māori health and well-being that produced many publications, Durie described how the three core areas overlapped, influenced, impacted, hindered, and improved the lives of Māori people. He continues to advocate for whānau to take control of life and live as Māori. The Māori Social Work practice operates in these core areas, for example, Māori require financial resources (economic development initiatives), to make informed decisions (political development initiatives), and live a healthy life (social development initiatives).

A social worker is unable to provide adequate social service to Māori without understanding their worldview. The reality, in the social work profession, is that Westerners need to be aware of how Māori development, matauranga Māori, and Māori Social Work are interrelated. Consequently, it is no longer acceptable for social workers to allege that they are ignorant of Māori culture, make excuses for not learning matauranga Māori, or decide to dismiss the vibrancy of Māori Social Work Theory.

Conclusion

Māori Social Work theory and practice is grounded in Māori principles. The practice will continue to evolve and reflect the

changes to government policy and Registration Board requirements. At the heart of Māori Social Work are the values aroha, awhi, kaitiakitanga, mahi, manaakitanga, and tautoko that are located in Te Ao Māori. Therefore, Māori would continue to provide social services regardless of money ensuring their tikanga and reo are not lost to the capitalist values of the Western world.

Understanding the history of Aotearoa assists social workers, work with Māori people. It is imperative to read the writings of an Indigenous population and build one's knowledge especially if a social worker is going to deliver a service to Indigenous people. Social workers must be aware of the impact from internal and external factors that occur in the social work profession, and determine ways to alleviate Māori people from the oppression they could be experiencing. This can be achieved through good community, tribal, and whānau relationships.

Whakawhanaungatanga is Māori Social Work in action. The positive relationships between agencies, institutions, communities, whānau, hapū, and Iwi are fundamental. Maintaining strong connections to the community, using tikanga and reo, are essential for constructive Māori Social Work. Also, realizing that whānau are the core to healing Māori families ensures Māori Social Work keeps true to Te Ao Māori because whānau are with a client before and after the social workers' job is completed. Therefore, applying a whanaungatanga technique is useful to the social worker, client, and their whānau.

Māori Social Work is unique to Aotearoa. New Zealanders, Māori and non-Māori, can take pride in knowing that this uniqueness sets their theory and practice apart from other countries. It provides an alternative application to social work literature, thought, and behavior that is not universal or global. That space has already been filled by Western knowledge. Instead, Māori Social Work can contribute to the growing discussions voiced by Indigenous people across the world and provide a guide for them to share their theories and practices. In conclusion, this article provided a range of descriptions to explain Māori social work.

Marital Quality and Health

Abstract

The protective effects of marriage on health are widely documented, yet recent research shows that these advantages are limited to high quality marriages. We describe the ways that marital quality affects a range of physical and mental health outcomes, with attention to gender, race, and life course differences therein. We also document how the effects of widowhood and divorce on health are moderated by the quality of the lost marriage. We highlight avenues for future research, including investigations of the linkages between relationship quality and health in cohabiting unions, same-sex partnerships, and remarriages.

The protective effects of marriage on health and well-being are widely documented. Studies dating back to Emile Durkheim's classic *Suicide* (1897) show that married persons enjoy better physical and mental health, including a lower risk of suicide, relative to their unmarried counterparts. Yet in recent decades, research has shown persuasively that all marriages are not equally beneficial, and that high quality marriages are particularly protective for health, well-being, and longevity – although the strength of this effect may vary by gender, race, and life course stage. In this article, we begin by defining 'marital quality' and 'health,' and show how these concepts are measured in empirical studies. Next, we describe how overall patterns of marital quality vary based on gender, race, and life course stage. We then describe key theoretical and methodological explanations for the protective effects of marital quality on health and well-being, and review recent empirical studies documenting statistical associations, with a focus on subgroup differences in the strengths of these patterns. Importantly, scholars have argued that one reason why marriage may be more beneficial to the health of men versus women, and whites versus blacks, is that men and whites typically report higher quality marital relations than their counterparts, and thus reap larger rewards. We also describe why and how the health-depleting effects of marital dissolution (i.e., divorce and widowhood) vary based on the quality of the dissolved marriage. Finally, we identify avenues for future research, and highlight the ways that research on marital quality and health can inform policies and practices to enhance well-being over the life course.

Marital Quality and Health: Concepts, Measures, and Methods

Marital Quality

Marital quality is a broad construct that encompasses a range of positive and negative marital interactions and perceptions. Its components may include interactions such as activities shared by the spouses, disagreements, and marital problems, as well as one's feelings toward their partner and level of satisfaction with the relationship. Some scholars go so far as to argue that divorce is the ultimate indicator of a poor quality marriage. Most empirical studies of marital quality focus on the specific dimensions of *marital happiness* or *satisfaction*, which are typically measured by asking an individual either a single question or a series of questions assessing how happy or satisfied one is with the marriage. Although satisfaction and happiness are conceptually similar, researchers draw the distinction that happiness taps one's feelings or emotions about the marriage, whereas satisfaction reflects a cognitive appraisal of one's relationship relative to some standard (e.g., what one hoped for in marriage, what others' marriages are like) (Campbell et al., 1976).

Most research on marital quality has focused on positively worded items such as "How happy are you in your marriage?" yet in recent years scholars have also assessed negatively worded items such as "my partner can get on my nerves," as well as the frequency of arguments and one's perceived likelihood that their marriage will dissolve. Researchers also may ask respondents to indicate how often they experience or how strongly they agree that a particular marital attribute characterizes their relationship. Items encompassing positive attributes typically refer to the amount of love, affection, support, and understanding one receives from one's spouse, whereas negative attributes include conflicts or excessive demands imposed by one's spouse. Scholars increasingly understand that positive and negative aspects of marriage are not opposite ends of a single pole; rather, positive and negative sentiments and interactions can coexist in a single relationship. For example, researchers have developed the measure of *marital ambivalence*, which encompasses high levels of positive and negative perceptions of one's spouse. This stands in stark contrast with *marital indifference*, which is marked by very low levels of both positive and negative sentiments (Fincham and Linfield, 1997).

Based on citations alone, the most widely used measure of marital quality is the Dyadic Adjustment Scale (Spanier, 1976), which comprises the subdimensions of troublesome dyadic differences, interpersonal tensions and personal anxiety, dyadic satisfaction, dyadic cohesion, and consensus on matters of importance to dyadic functioning (Spanier, 1976: p. 17). Other widely used measures include the Short Marital Adjustment Test (Locke and Wallace, 1959), and single-item global

measures such as "Taking things all together, how would you describe your marriage?"

Health

Most studies of marital quality and health rely on large random-sample surveys that obtain self-reported measures of physical and mental health, as well as the marital quality items described above. Researchers can then explore statistical associations between one's marital quality appraisals and self-reported health measures in order to understand linkages between the two. Health can be defined as the "state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (World Health Organization, 2006). Consistent with this definition, studies of marital quality and health cast a wide net, linking marital characteristics to physical health outcomes including mortality risk and risk of particular diseases (e.g., heart disease, diabetes, and cancer) and health symptoms (e.g., high blood pressure, sleep problems); mental health outcomes such as depressive symptoms, anxiety, and substance use; and measures of social well-being like life satisfaction, psychological well-being, and self-esteem (Proulx et al., 2007).

One of the most important advances in the past two decades has been linking marital quality to physiological markers of health called 'biomarkers.' A growing number of population-based surveys now obtain biological indicators that provide information on one's cardiovascular functioning (e.g., blood pressure readings), endocrine systems (e.g., cortisol levels), and immune function (e.g., natural killer cell lysis); each of these biomarkers is associated with the development of particular diseases (Robles and Kiecolt-Glaser, 2003). Major surveys in the United States such as the Midlife in the United States (MIDUS), National Social Life, Health, and Aging (NSHAP), and Wisconsin Longitudinal Study (WLS) obtain detailed self-reports of one's marriage, physical health, and mental health, as well as biological measures such as heart rate and levels of stress hormones associated with the development of chronic diseases.

Mounting research also explores marital quality and health in laboratory settings. In such studies, researchers might induce a marital spat, and then explore whether the induced threat to marital quality affects physiological markers associated with illness, such as blood pressure, cortisol levels, or the speed with which a laboratory-induced injury will heal. For example, a team of researchers at Ohio State University brought into their laboratory 42 healthy married couples, whose ages ranged from 20 to 80. When the study started, the researchers gave each spouse a small (though relatively painless) cut on their forearm. Some study participants were then told to discuss a potentially contentious topic with their spouse, such as in-law woes or financial worries. The researchers found that the couples with the most heated arguments had significantly slower wound-healing, evidenced by how quickly the small forearm cut healed. Most subjects healed within 5 days, but those who had a heated discussion with their spouse took 1 full day more to heal. The researchers also obtained information on how the couple interacted during the argument. They videotaped the arguments and rated how 'hostile' the exchanges were; those couples rated as being hostile toward one another took fully 7 days to heal (Kiecolt-Glaser et al., 2005). Taken together, these studies reveal the broad range of measures and methods used to identify linkages between marital quality and health.

Subgroup Differences in Marital Quality

Before further delving into linkages between marital quality and health, it is important to first review social factors that affect marital quality. Patterns vary slightly based on the samples and methods used, yet most studies conclude that men, whites, and newlyweds report higher levels of marital quality than women, blacks, and longer-married persons, respectively. The former two differences, in particular, may partly explain why marriage is generally more protective for the health of men and whites, relative to blacks and women; those who experience the most rewarding marriages will reap the most profound health benefits. We briefly describe subgroup differences in marital quality, and potential explanations for these differentials.

Gender

One of the most widely documented findings in marital quality research is that women report lower levels of marital quality and satisfaction than men, although the magnitude of these differences is modest (Jackson et al., 2014). The main explanations given for women's slightly lower marital quality ratings relative to men's are: women's lower levels of power in marital relations; their elevated risk of experiencing domestic violence or mistreatment; the disproportionate burden that women bear regarding child care, housework, and other tasks essential to maintaining a household; their greater emotional investment in sustaining a successful marriage; and their greater willingness to acknowledge and address problems in the marriage (Jackson et al., 2014).

Race and Ethnicity

Surprisingly few studies have explored race and ethnic differences in marital quality, with most of this work focusing on black–white differences. Most studies conclude that blacks report higher levels of marital conflict and strain, higher rates of divorce, and lower levels of marital satisfaction than their white counterparts (Broman, 2005). The main explanations for these gaps focus on behaviors within the marriage, where blacks report more frequent fighting, substance use, and infidelity than their white counterparts (Broman, 2005). Blacks' elevated risk of socioeconomic adversities also may take a toll on one's marriage; stressors like unemployment, discrimination, and financial strain may contribute to marital tensions (Corra et al., 2009). Few studies focus on marital quality among Latinos, yet there is mounting evidence that Mexican-Americans report significantly higher levels of marital quality than blacks, although both subgroups experience elevated risk of socioeconomic adversities. Mexican-Americans' relatively high quality marriages are attributed to a familistic pro-marriage culture that supports and sustains marriage in many Latino communities (Bulanda and Brown, 2006). The high quality marriages documented among Mexican-Americans also may

contribute to the well-known 'Latino paradox' in health; Mexicans report relatively good health, despite their poor economic status compared to whites – perhaps due to the health-enhancing benefits received by their strong marriages.

Marital Duration

Marital quality changes with the duration of marriage, where satisfaction waxes and wanes over time, as expectations and social roles change (Brown et al., 2013). The family life cycle explanation suggests that marital satisfaction is high in the very early stages of a marriage (e.g., 'the honeymoon stage'), and then declines as the spouses face increasing demands with work, childrearing, and home-making. As these stressors diminish over time, marital quality tends to increase in the later years of marriage, once children have left the family home. This is also described as a U-shaped curve (Orbuch et al., 1996). By contrast, a second conceptual model called the disillusionment model presumes that newlyweds hold onto idealized views of their partners, yet after the honeymoon stage passes, spouses may become disappointed, disillusioned, or upset with one another. Whereas the life cycle model posits a U-shaped curve, the disillusionment model presumes that marital quality will either continue to decline, or the marriage will be terminated. Finally, the enduring dynamics model or maintenance hypothesis counters that while unrealistic expectations may be dashed in the early stages of marriage and marital quality may dip after the initial heady years, quality remains relatively steady thereafter, as the partners adjust their expectations to the realities of their lives (Brown et al., 2013).

Marital Quality and Health: Theoretical and Methodological Explanations

Why and how does marital quality affect health? Three main classes of explanations are offered: (1) social explanations emphasize the emotional support and health-enhancing assistance exchanged in high quality marriages (e.g., Umberson et al., 2006); (2) biological explanations focus on physiological responses to close and nurturing relationships (e.g., Robles and Kiecolt-Glaser, 2003); and (3) methodological explanations emphasize the concept of 'social selection,' where those with better health are predisposed to experiencing more satisfying and enduring marriages (e.g., Butterworth and Rodgers, 2006).

Social Support and Integration

High quality social relationships, in general, and marital relations, in particular, are a well-documented source of positive health (Robles et al., 2014). A high quality marriage can provide the sense of security and emotional support that helps to bolster mental health. Happily married persons also enjoy more satisfying and frequent sexual relations, which provide physical and emotional health benefits (Galinsky and Waite, 2014).

Marriage, especially high quality marriage, is also considered a source of 'social control' (Umberson et al., 2006). Spouses who love and care about one another will encourage the adoption of healthy behaviors and the loss of unhealthy ones. Husbands and wives may encourage each other to eat nutritious meals, to take their daily medications, to eschew or limit their smoking and alcohol consumption, and to engage in health-enhancing physical activities together. By contrast, persons in poor quality marriages are more likely to engage in risky health behaviors. Persons in unhappy marriages exhibit poor eating habits, erratic sleep patterns, and higher rates of smoking, alcohol use, and nonmedical use of prescription medications (Miller et al., 2013).

A high quality marriage also can protect against or 'buffer' the potentially health-depleting effects of stressors like unemployment, work strains, and illness (Cohen and Wills, 1985). For example, several studies of older married couples found that persons with high levels of physical disability, functional impairment, and impaired vision were far less likely to be depressed if they enjoyed high quality marriages, yet were more likely to be depressed if they were in marriages marked by frequent arguments and disagreements (Bookwala, 2011). Thus, marital quality can be a powerful resource that protects against mental health declines, especially as couples face the physical challenges of aging.

Biological Pathways

One of the most important scholarly advances of the past two decades has been the exploration of the physiological pathways through which marital interactions 'get under our skin' and affect physical health (Ryff and Singer, 1998: p. 214). The pathways most often considered are those that progress through multiple physiological systems, including cardiovascular, endocrine, immune, metabolic, and sympathetic nervous systems (Robles et al., 2014).

For example, laboratory studies show that maintaining physical contact and closeness with one's spouse when placed under a stressful experimental condition leads to decreases in blood pressure and heart rate, and an increase in the hormone oxytocin. Oxytocin weakens the potentially harmful impact of stress on cardiovascular and endocrine systems (Light et al., 2005). Similarly, in another laboratory study, women who held their husband's hand while experiencing painful electric shocks reported less pain, and showed decreased activity in the brain region responsible for directing the body's stress response. By contrast, women who held either a stranger's hand or no one's hand (control group) did not evidence such positive physiological responses, underscoring the distinctive effects of the marital relationship (Coan et al., 2006).

Negative interactions, such as marital strain and hostility, also compromise immune system responses (Robles and Kiecolt-Glaser, 2003). The immune system protects the body from bacteria and viruses by releasing antibodies and white blood cells into the circulatory system. In one experimental study, happily married couples were prompted to argue about a 'real problem' that they disagreed about. Spouses who showed supportive and constructive behaviors during the argument evidenced reduced stress hormone levels, with steeper effects among wives than husbands. Similarly, a prospective study of older persons in long-term marriages marked by higher levels of conflict and frequent negative behaviors evidenced significantly worse immune system

responses, compared to persons in marriages marked by low conflict and negative behaviors. Taken together, these studies reveal that couples who show the least negativity and most positivity in their marital relations enjoy the healthiest immune, cardiovascular, and endocrine system responses.

Social Selection

Thus far, the theories and data we have reviewed suggest that marital happiness can protect health, whereas marital conflict can hurt. Yet a mounting body of research suggests that marital quality and health may be mutually influential, and that poor physical and mental health may impede both one's own and one's spouse's assessment of marital quality. Physical health problems may put a damper on a married couple's sexual relationship, and may also place difficult caregiving demands on the healthier partner, thus compromising marital quality (Pinquart and Sorensen, 2011). Health problems may also affect one's ability to maintain steady work, which in turn may place financial strains on the couple. Mental health problems also may compromise a marriage. An emotionally volatile or depressed spouse may not be able to provide their partner the love, attention, and support they desire. Likewise, a spouse with a substance use disorder in particular may be likely to abuse their partner emotionally or physically, and may not contribute effectively to the daily household chores and activities that are at the centerpiece of a good marriage. Consistent with the notion that health problems may suppress marital quality, several studies have documented an elevated risk of divorce in couples where one or both spouses have a series physical or mental health condition (e.g., Butterworth and Rodgers, 2006).

Marital Quality and Health: Subgroup Differences

Gender

Does marital quality have more powerful effects on the health and well-being of women or men? Research is equivocal, with clinical and laboratory-based studies generally finding greater female vulnerability to marital strain, and population-based studies detecting few if any gender differences (Umberson and Williams, 2005). For example, some studies show that women experience greater physiological arousal in response to laboratory-induced arguments than do men, and this greater arousal, in turn, may have deleterious consequences for their physical health (Robles and Kiecolt-Glaser, 2003). Similarly, prospective studies of congestive heart failure patients show that marital quality is a stronger predictor of survival among women than men (Coyne et al., 2001). By contrast, survey-based studies and a recent meta-analysis (Robles et al., 2014) find relatively weak evidence of gender differences.

To the extent that gender differences exist, scholars have posited several explanations for the stronger linkages among women. First, interpersonal relationships, especially marriage, are considered more highly salient to the self-concept of women – whereas work-related accomplishments are considered more salient to the identities of men. As such, women may be more aware of and responsive to a relationship's ups and downs, and may evidence greater physiological responses to stressors related to their marriage (Robles et al., 2014). Second, some argue that women have lower social status than men in society, and this power imbalance follows men and women into marriage. Low status, in turn, is associated with greater levels of stress reactivity; thus, women may react more strongly to marital strains and suffer the health consequences thereof (Wanic and Kulik, 2011).

Race

Surprisingly little research has explored whether the ties between marital quality and health vary by race and ethnicity. This is an important omission. Some scholars have proposed that the well-documented black–white gap in nearly every health outcome ranging from mortality to cardiovascular disease to diabetes is partially due to the fact that blacks are less likely than whites both to be married, and to maintain high quality marriages. However, little is known about whether a high quality marriage provides richer health benefits to blacks versus whites.

Some scholars have argued that high quality marriage may be less protective (and strained marriages less deleterious) to the health of blacks versus whites because marriage may be less salient to blacks than whites. For example, blacks' social networks include a higher proportion of persons from their religious community and extended family, relative to whites. These networks may provide many of the supports that might otherwise be provided by spouses (Levin et al., 1994). However, one recent review of the literature concluded that marital quality figures equally into the health of blacks and whites (Blackman et al., 2005).

Life Course Stage

Mounting research shows that the protective effects of marital quality on health vary over the life course. In particular, the deleterious effects of marital strain on health intensify with age (Umberson et al., 2006). These findings are consistent with the core themes of socioemotional selectivity theory; this perspective holds that as adults grow older and their time horizons constrict, their closest relationships (such as marriage) become more salient to them than their other more distant social ties (Carstensen, 1991). Moreover, age-related biological vulnerabilities also explain these patterns; immunological impairment increases with age, and the stress associated with marital strain may further accelerate aging of the immune system (Kiecolt-Glaser and Glaser, 2001). Finally, cumulative advantage perspectives argue that the harmful consequences of exposure to stress may accumulate over time, rendering unhappily married older adults more vulnerable from the 'wear and tear' that they have experienced over the life course (Dannefer, 2003).

Marital Dissolution and Health: Does Marital Quality Matter?

Research consistently shows that widowed and divorced persons have poorer physical and mental health than their married counterparts, with effects documented for

diverse outcomes including self-rated health, mortality risk, cardiovascular disease, smoking-related cancers, functional limitations, chronic conditions, depression risk, and problem drinking (Hughes and Waite, 2009; Zhang and Hayward, 2006).

However, the health-depleting effects of marital dissolution are contingent upon the quality of the marriage that has been lost. Although early studies presumed that the stress surrounding spousal death or divorce would overwhelm one's ability to cope and thus impair one's health, more recent work recognizes that one's marital 'role history' must be taken into consideration. Sociologist Blair Wheaton (1990) observed that exiting a social role that provided relatively few rewards, such as a conflicted and unhappy marriage, may not lead to distress but may instead be a source of mental and physical uplift.

Empirical studies in generally support Wheaton's assertions. Several studies have tracked the health of persons who dissolved troubled marriages, and found physical and mental health gains among those who exited bad marriages, yet health decrements among those who remained married (Hawkins and Booth, 2005; Williams and Umberson, 2004). The authors concluded that dissolving an unhappy marriage may be more protective to one's well-being than staying married. However, other studies have found that exiting a troubled marriage does not enhance one's mental health, and in fact, may be worse than remaining in the strained marriage (e.g., Kalmijn and Monden, 2006). The authors did not argue that individuals should remain in problematic marriages; rather, many of the strains of a problematic marriage may persist after the dissolution, particularly when ex-spouses must negotiate difficult custody or financial issues.

Marital dissolutions due to spousal death are distinct from those due to divorce, as widowhood is almost always entered into involuntarily, whereas divorce is typically desired by at least one of the two partners. However, research on widowhood – like divorce – shows that the emotional toll of dissolution varies based on the quality of the late marriage. For example, Carr et al. (2000) investigated whether bereaved older adults' psychological adjustment to loss varied based on the levels of warmth, conflict, emotional dependence, and instrumental dependence the survivor had experienced in the marriage. They found that persons in very close and warm relationships experienced elevated grief symptoms, as they were exiting a social role that had provided rich emotional rewards.

Conclusions and Future Directions

Marital quality is protective for adult well-being because high quality marriages provide emotional and instrumental support as well as physiological rewards that enhance physical and mental health. Yet researchers continue to grapple with unanswered questions regarding marital quality and health. First, research on marriage and health generally shows that first marriages are more protective than are higher-order marriages (i.e., remarriages), cohabiting unions, and long-term same-sex relationships. One explanation offered for these patterns is that different types of unions provide different socioemotional benefits that, in turn, protect one's health and well-being. However, few studies recognize that relationship quality may vary widely even within particular types of unions; we urge researchers to identify the specific aspects of marital interactions in remarriages, same-sex unions, cohabiting unions, and dating relationships that are protective for health.

A second limitation of extant research is that most studies focus on the associations between one individual's marital quality assessments and his or her health, with little attention paid to the partner's views of the marriage. Husbands' and wives' reports of marital quality vary widely, typically yielding correlations of just 0.50 to 0.60 (Carr and Boerner, 2009). As such, researchers are increasingly interested in 'crossover' or 'partner' effects; this research explores whether one partner's reports of marital satisfaction affect the other spouse's health and well-being. For example, an unhappily married spouse may be less motivated to provide his or her partner with the emotional support and caregiving that enhances the partner's health. The development of statistical techniques like actor–partner independence models (Kenny et al., 2006), as well as the collection of couple-level data in large-scale sample surveys like the NSHAP, WLS, and Disability and Use of Time (DUST) daily diary supplement to the Panel Study of Income Dynamics, now enable researchers to explore how one's own health is linked to one's spouse's level of satisfaction and happiness in the marriage (Carr et al., 2014).

Understanding the complex ways that marital interactions affect health (and vice versa) is important from a public policy perspective. In the early 2000s, policy makers believed that being married was protective to the well-being of spouses and their children, thus President George H.W. Bush's administration supported social programs to encourage marriage. Yet in recent years, scholars have documented that not all marriage is good marriage, and that high quality marriages are protective for health. This research has triggered investment in programs aimed at enhancing communication, closeness, and cooperation in marriages (Staton, 2009). Interventions to facilitate communication, minimize conflict, and uphold high quality marriage may be an essential step to protecting the health of adults in the United States.

Marital Status, Divorce, and Child Development

Colleen M Carr and Sharlene A Wolchik, Arizona State University, Phoenix, AZ, USA

Abstract

A significant proportion of children and adolescents experience parental divorce, and much research has focused on the impact of divorce on children's adjustment outcomes. This article reviews data on the prevalence of divorce and changes in divorce rates over time, summarizes results of literature on children's postdivorce adjustment outcomes, discusses societal costs of parental divorce, outlines theories of the effects of parental divorce, and describes factors associated with children's responses to parental divorce. The article concludes with a discussion of interventions shown to prevent or reduce children's postdivorce adjustment problems.

Different Societal Views of Divorce

To understand the impact of divorce on children's adjustment problems and well being, it is valuable to consider diversity in cultural attitudes toward divorce. Generally, individualistic (typically Western) societies have more favorable attitudes toward divorce than do collectivist societies. In individualistic cultures like the United States, it is normative for people to opt out of marriages that no longer enhance their self-interest or enable high levels of self-discovery and self-disclosure. Despite divorce being a common experience in the United States, it has long been associated with stigma. This stigma is reflected in the research in the 1960 and 1970s, in which divorced families were described as 'broken' and married families were described as 'ideal' or 'intact' families. Less stigma is associated with divorce in some European countries, like Scandinavian countries, which have liberal attitudes toward divorce and diverse family structures. In collectivist cultures like China, divorce is seen as violating traditional Confucian values that emphasize the centrality of family and interpersonal harmony. In these cultures, people tend to adhere to tradition and social convention, which often includes respecting parents' preferences for partner selection and religious rules regarding maintenance of marriage. In such societies, individuals are less likely than in other cultures to divorce even when the marriage is unsatisfying. Although divorce is still associated with intense stigma and shame in China, recently, the divorce rate has increased in regions that have experienced industrialization and modernization.

Demographics of Divorce

Different cultural attitudes about divorce are reflected in wide variation in divorce rates across the world. Crude divorce rates, which reflect the number of divorces per 1000 people, are higher in the United States than in other nations. In 2011, the crude divorce rate in the United States was 3.6, compared with rates ranging from 2.0 to 2.3 in Japan, France, Germany, and the United Kingdom. Crude divorce rates are typically lower in less developed countries. For example, rates are 0.8 in Mexico, 2.0 in China, and range from 1.4 to 1.9 in most reporting African nations.

Crude divorce rates are not an ideal method of assessing divorce rates because they do not account for the proportion of populations consisting of children and single adults. An alternative method is to consider the percentage of marriages that end in divorce. Recent estimates show that in some countries, the rate of marriages ending in divorce is almost as high if not higher than in the United States, where 53% of marriages end in divorce. For example, 55% of marriages in France, 47% in the United Kingdom, and 49% of marriages in Germany end in divorce. Rates are lower in Japan (36%), China (22%), and Mexico (15%). Although divorce rates vary among families of different demographic profiles, between 30–40% and 48% of American and British children, respectively, are expected to live in a divorced, single-parent home by age 16. Recent data from Australia revealed that only 25% of young adults reported having experienced parental divorce in childhood. Not only is divorce a common experience for children across nations, but often the divorce rate for remarriages is higher than for first marriages. Thus, a sizable number of children who experience parental divorce will experience more than one transition in family structure.

Risks Conferred by Parental Divorce

The majority of research examining children's responses to parental divorce has been conducted in the United States, and the current review summarizes this research as well as the less extensive research conducted in other countries. Commonly, researchers have compared outcomes at a single point in time of children who have experienced parental divorce with those of children who live with both of their biological parents. Some researchers have followed children at multiple points after divorce or assessed children's outcomes before and after divorce. A few researchers have assessed whether children's outcomes improve through participation in preventive interventions designed to change factors associated with children's postdivorce outcomes.

Improved research methodology in recent decades has allowed researchers to adequately control for variables that influence parental divorce and children's adjustment outcomes. For example, fixed-effect models account for time invariant sources of heterogeneity, genetically informed studies

account for the influence of shared genes, and randomized experimental trials of preventive interventions account for variables that are naturally correlated in nonexperimental studies (e.g., maternal personality, preexisting economic stress). Results from research using these methods have highlighted the great variability in children's responses and identified aspects of the circumstances faced by families before and after the actual marital dissolution that affect children's post-divorce adjustment outcomes.

For most children and adolescents, the separation period itself causes considerable stress, and during the first year or two after separation, many children experience distress, anxiety, anger, and disbelief about the divorce. However, most children 'bounce back' during the first couple of years after the divorce.

Although research in the United States shows that 70–75% of children who experience parental divorce do *not* have clinically significant mental health problems (e.g., Hetherington et al., 1998), there is compelling evidence demonstrating that divorce increases risk for mental health problems in childhood and adolescence. The most comprehensive picture of how children fare after parental divorce is provided by results of *meta*-analysis, a quantitative method of literature review in which measures of central tendency (e.g., the mean) and variation of outcomes are aggregated from multiple studies. *Meta*-analyses of 92 studies published mostly in the United States through the 1980s (Amato and Keith, 1991) and 67 studies published in the 1990s (Amato, 2001) showed that children in divorced families were more likely to exhibit externalizing problems, such as conduct disorders, delinquency, and impulsive behavior than children in two-parent families. Although the largest differences were found for externalizing problems, children from divorced families were also more prone to experience internalizing problems, such as depression and anxiety, than children from married families. These differences were consistent across children's age and gender and were slightly larger for more recent studies. It is important to note that the differences in adjustment outcomes of children from divorced versus married families were small to moderate in magnitude.

Similar results have been found cross-culturally. A large-scale study in Norway revealed that although most children who experienced parental divorce fared fine, a subgroup had more externalizing problems and difficulties with peers and, to a lesser extent, more internalizing problems than youths from two-parent families. Similarly, research in Turkey, where 20% of marriages end in divorce, has shown that girls whose parents divorced experienced higher depression levels than children in married families, and both boys and girls from divorced families exhibited more psychological problems than youths in married families. Furthermore, research in China has found that, compared with children with married parents, children who experienced parental divorce exhibited more behavioral problems and increased rates of anxiety and depression.

Research also shows that children whose parents divorce perform less well academically, score lower on achievement tests, and are more likely to drop out of school than children with married parents. For example, analyses of 10 U.S. national probability samples revealed school dropout rates of 31% among adolescents who experienced parental divorce compared with 13% in nondivorced families (McLanahan, 1999). Similarly, the Longitudinal Study of Australian Youth found that 22% of youths from single-parent and divorced families did not complete high school, compared with 13% from two-parent families (Curtis and McMillan, 2008). Furthermore, research in Scandinavia showed that youths in divorced families achieved lower grade point averages than their peers with married parents. And, research in China has found that parental divorce is associated with decreased school performance.

Children from divorced homes are more likely to engage in risky behaviors, such as substance use and early sexual activity. Adolescents from divorced families in the United States initiate alcohol use earlier and report higher alcohol, marijuana, tobacco, and illicit drug use than their peers from two-parent families. Similarly, researchers have found that Scandinavian youths who experienced parental divorce were more likely to smoke, consume alcohol, and use illicit drugs than their peers in two-parent families. Research also shows that adolescents whose parents are separated or divorced engaged in intercourse at younger ages than those whose parents are married. Compared with adolescents whose parents remained together or divorced later in their childhood, adolescents in the United States whose parents divorced when they were 5 years or below were at particularly high risk for engaging in sexual activity by age 16 (Donahue et al., 2010). Early parental separation is also associated with a greater number of sexual partners in adolescence. Furthermore, adolescents from divorced families in the United States experience teen birth rates of 33% compared with 11% among adolescents from nondivorced families (McLanahan, 1999). Similarly, research shows that adolescent females in divorced families in New Zealand are more likely to experience teenage pregnancy than their peers in married families.

Parental divorce might either initiate new difficulties or exacerbate existing ones. Some studies that have assessed children prior to parental divorce have shown that problem behaviors are evident well before marital dissolution. In addition, some studies show that differences between children who have and have not experienced parental divorce are diminished after controlling for predivorce functioning. It is important to note, however, that several other studies show a significant increase in problems among offspring of divorced parents after divorce after controlling for predivorce factors.

As noted earlier, although *most* children do not experience significant lasting problems following parental divorce, negative effects of parental divorce extend into adulthood for a substantial minority. Several prospective studies with epidemiologic samples have revealed an association between parental divorce and significant increases in mental health problems, substance abuse, mental health service use, and psychiatric hospitalization in adulthood. For example, Chase-Lansdale et al. (1995) reported that the odds of exhibiting clinically significant mental health problems at age 23 increased by 39% as a function of parental divorce after controlling for relevant predivorce variables like emotional problems, academic achievement, and socioeconomic status. More recently, the World Mental Health Survey revealed that after controlling for age, country, and type of disorder, parental divorce was associated with elevated rates of onset of mental

health disorders in adulthood in high-, middle-, and low-income countries (odds ratio 1.1–1.3) (Kessler et al., 2010).

Research also shows that the effects of parental divorce in adulthood extend beyond mental health problems. Many studies provide evidence that parental divorce in childhood is related to less success in key developmental tasks of young adulthood: education, work, and romantic relationships. Adults who experienced divorce in childhood have lower educational and occupational attainment and more economic and employment problems. Also, adults who experienced parental divorce in childhood experience poorer marital quality and are more likely to divorce, a phenomenon referred to as the 'intergenerational transmission of divorce.' Furthermore, parental divorce in childhood is associated with increased physical health problems in adulthood. Illustratively, a 70-year prospective study found that experiencing parental divorce before age 21 was related to a 44% increase in mortality risk, controlling for personality in childhood and individuals' own divorces (Schwartz et al., 1995).

Summary

Overall, research indicates that a substantial minority of children who experience parental divorce are at increased risk for a variety of difficulties in multiple domains of functioning. Specifically, in childhood and adolescence, youths who experience parental divorce are at heightened risk for internalizing problems, externalizing problems, reduced academic achievement, school dropout, substance use, and early sexual behavior. Adults who experienced parental divorce in childhood are at increased risk for experiencing mental health disorders, physical health problems, reduced educational and occupational achievement, poorer marital quality, and divorce.

Societal Costs of Parental Divorce

The divorce process and its immediate ramifications often place economic demands not only on the divorcing individuals, but also on society. Divorce-related policies vary tremendously among countries, with some nations, including many European nations, providing aid to single mothers that is intended to offset the negative economic impact of divorce. For instance, some states fund generous public childcare programs, which enable single mothers to more easily reenter the workforce. Nations that provide high levels of social welfare, like Belgium, Denmark, and the United Kingdom, indirectly pay high costs for parental divorce by funding such systems.

The long-term effects of parental divorce on youths' adjustment outcomes also have negative economic effects. Although the typical magnitude of differences in adjustment outcomes between individuals who experienced parental divorce in childhood and those who did not is not large, the short- and long-term outcomes associated with parental divorce, such as internalizing problems, externalizing problems, and substance use problems, have high societal costs. For instance, children's externalizing problems like antisocial behavior, aggression, and delinquency are related to unemployment and criminality in adulthood, which cost the United States between $335 and $350 billion annually (Miller, 2004). Also, internalizing problems, such as depression, cost the United States over $83 billion in medical services, lost lifetime earnings due to suicide, and lost workplace productivity (Greenberg et al., 2003).

The concept of population attributable fraction (proportion of an outcome due to a risk factor or percentage of cases that could be prevented by removing the factor or its consequences (PAF)) provides an important perspective on the public health significance of parental divorce. Results from a nationally representative survey of adults in the United States revealed that the PAF of parental divorce for drug dependence is 23%, suggesting that almost one-quarter of cases of drug dependence could be eliminated by reducing the negative effects of parental divorce.

Given that the effects of parental divorce are similar cross-culturally, we would expect the economic costs of divorce to be high worldwide, particularly among nations with high divorce rates. For instance, evidence from the Netherlands, where 43% of marriages end in divorce, showed that parental separation or divorce is one of 10 major adverse childhood experiences associated with a variety of emotional problems, health risks, disease burden, sexual health issues, disability, and healthcare costs that have significant public health burden.

Theories of Children's Responses to Parental Divorce

There are two main theoretical perspectives for understanding the risks conferred by parental divorce. The genetic model focuses on the genetic transmission of personality traits. The transactional model suggests that the constellation of stressful events associated with separation and divorce adversely affects children's adjustment outcomes.

The passive genetic model posits that personality traits of parents contribute to both divorce and children's adjustment problems. According to this view, some parents have genetic predispositions for traits like aggression and antisocial behavior that increase the risk of family conflict and divorce. Furthermore, offspring of these parents inherit traits that increase the probability of developing adjustment problems, such as externalizing problems. Results of twin and adoption studies have shown that although some of the outcomes associated with parental divorce, such as internalizing problems, might be due to genetic factors, the majority of children's postdivorce adjustment problems, including externalizing problems and substance use, cannot be explained by passive genetic inheritance.

In the transactional model of divorce, changes in family relationships and environmental circumstances before and after separation and divorce, rather than divorce itself, are viewed as critical determinants of children's postdivorce adjustment problems. Factors that are present prior to divorce include characteristics of parents themselves, their parenting behaviors, and economic conditions. Research indicates that parents who divorce are more likely to have a history of alcoholism, depression, antisocial behavior, and economic problems. Couples who divorce also have poorer conflict resolution

skills, higher levels of negativity, and poorer parenting skills prior to the divorce than married couples.

Stressful events that occur during separation and divorce and the availability of protective factors are seen as influencing the extent to which children are adversely affected by parental divorce. The stressful changes that occur for many children include increases in interparental conflict and parental depression, reductions in contact with the nonresidential parent and relatives, changes in residence, and reductions of material resources. These changes influence adjustment problems to the extent that they are mitigated by interpersonal protective factors, such as high-quality parent–child relationships, and intrapersonal protective factors, such as effective coping skills. For example, high-quality parent–child relationships might moderate, or reduce the strength of, the relation between interparental conflict and adjustment problems.

From this perspective, divorce can lead to an unfolding of failures to resolve developmental tasks and can increase susceptibility to mental health problems and impaired competencies that can persist over developmental stages. Parenting is viewed as playing a central role in facilitating children's successful adaptation. Furthermore, the skills and resources that are developed in successful resolution of developmental tasks, such as effective coping and academic success, are viewed as important tools when children face challenges in subsequent developmental periods. Dynamic interactions between children's resources and their developing competencies can lead to a positive or negative cascade of adaptive functioning in multiple domains over time. For example, high-quality parent–child relationships might lead to lower levels of externalizing problems, which might increase the likelihood of positive interactions with mothers, fathers, teachers, and peers, which could lead to further reductions in externalizing problems and improvements in other aspects of functioning, such as social competence. Alternatively, low-quality parent–child relationships might lead to higher levels of externalizing problems, which might increase the likelihood of negative interactions with mothers, fathers, teachers, and peers, which could lead to further increases in externalizing problems and impairments in social competence.

Summary

Although some of the difficulties exhibited by children after divorce are likely due in part to a genetic predisposition for developing these problems, environmental, intrapersonal, and interpersonal factors also likely influence children's post-divorce adjustment outcomes. In the next section, we discuss factors that have been shown consistently to be related to children's postdivorce adjustment outcomes.

Understanding Variability in Children's Postdivorce Adjustment Outcomes

In the context of the significant public health burden associated with parental divorce, variability in children's outcomes has prompted researchers to examine factors affecting children's postdivorce outcomes. This research has guided the development of interventions by identifying factors to target for change.

Stressful Events

As discussed above, parental divorce involves a multitude of potential stressful changes and disruptions in children's social and physical environments that occur before, during, and after parental separation. For example, interparental conflict often begins many months or years prior to separation. Conflict can escalate during the processes of separation and divorce as parents negotiate new parenting-related issues, such as residential and visitation arrangements and child support.

Children, parents, and clinicians who work with children from divorced families agree that the most stressful divorce-related experiences are those that occur in the nuclear family. These include verbal and/or physical interparental conflict, derogation of one parent by another, and being blamed for the divorce. Other experiences that children perceive as highly stressful include hearing criticism of their parents by relatives or neighbors, having to give up material possessions, and being exposed to maternal psychological distress.

Most children experience changes in their relationships with their parents during the divorce process. Although there has been an increase in joint residential arrangements over the past couple of decades, about 80% of children in divorced families in the United States live primarily with their mothers. Similarly, research on separated and divorced parents shows that 84% of mothers in Australia identified themselves as the primary residential parent, compared with 17% of fathers. Thus, parental divorce often means that children lose daily contact with fathers. Australian data show that half of children who live apart from one of their parents, typically fathers, see their nonresidential parent at least every other week. Statistics from the United Kingdom show that at least half of children whose parents separated or divorced had weekly contact with their nonresidential parent, although fewer than 30% had weekly overnight stays with their nonresidential parent. Research shows that for many children, contact with nonresidential fathers decreases substantially over time. For most children, the quality of the father–child relationship also changes following separation as fathers adapt to new parenting responsibilities and both children and father adjust to new living arrangements. Specifically, researchers have found that many children feel less close to their fathers and children after the divorce and fathers have difficulty providing consistent discipline and setting limits for their children.

Separation and divorce also affect children's relationships with their mothers. Primary residential mothers report high levels of stress as they negotiate the tasks of adjusting to the dissolution of marriage and managing additional household and childcare responsibilities. Juggling these demands increases mothers' risk for psychological distress, which has been linked to disruptions in parenting. After separation and divorce, mothers are often less supportive and affectionate and less consistent and effective in their discipline strategies.

Many newly divorced parents experience a decrease in family income. Researchers in Australia have found that even with increases in government income support and increased job opportunities for women in recent decades, women and

children in particular continue to be significantly negatively impacted by postdivorce financial hardships. Reductions in standard of living after divorce often lead to stressful changes for children, including having fewer material resources, moving to smaller homes, changing neighborhoods, and changing schools. These transitions can involve the loss of relationships with friends, teachers, and other important members of children's social support networks. In some nations, like Scandinavian welfare states, families are less financially impacted by divorce. However, research suggests that children in these societies do not fare better following divorce than children from societies that provide little or no financial support to families postdivorce. This finding suggests that financial stressors are only one factor influencing children's postdivorce outcomes.

For many children, parental divorce is followed by additional family transitions. Most adults remarry following divorce, and the median time between divorce and remarriage is 4–5 years in the United States (U.S. Census Bureau Marriage and Divorce, http://www.census.gov/). Half of these newly formed households include children under age 18. Furthermore, many children become part of new families through cohabitation rather than remarriage. Although remarriage or cohabitation can increase the financial and emotional support provided to the residential parent, remarriage or cohabitation alters the nature of children's relationships with their biological parents and often involves a complex family reconfiguration. For children, this includes the addition of a stepparent, as well as other step–kin relations with stepsiblings, grandparents, and other extended family and, in some cases, half-siblings.

The frequency of divorce-related changes relates positively to internalizing and externalizing problems and negatively to self-concept, social competence, and academic competence. Children exposed to more divorce-related stressors also show maladaptive cognitions, including a reduced sense of their ability to affect their environments, than those exposed to fewer divorce-related stressors.

Interparental Conflict

Although a large body of research has shown that interparental conflict is one of the most damaging aspects of divorce, research has shown that children in families characterized by intense, chronic marital conflict and/or violence are better off in the long run if their parents divorce. Although many children whose parents divorce have been exposed to high levels of interparental conflict prior to divorce, in approximately 25% of divorcing families, parents exhibited minimal conflict before separating.

Conflict is a complex construct, and interparental conflict's effect on children's adjustment outcomes depends on several factors, such as intensity and whether or not the child witnesses the conflict. Intensity of conflict is positively related to infants' and toddlers' anxiety and insecure attachment and to young children's distress and insecurity. In older children and adolescents, intensity of conflict is positively related to increases in internalizing problems and externalizing problems. Overt hostility between parents, which can involve slapping, screaming, and derisive behavior, is more strongly associated with externalizing problems and internalizing problems than passive–aggressive hostile behavior between parents. However, passive–aggressive conflict and subtle behaviors that put children in the middle can also be problematic and are linked to children's internalizing symptoms like depression, anxiety, and withdrawal.

Parenting

Most of the research on relations between parenting and children's postdivorce adjustment outcomes has focused on mother–child relationships. Father–child relationships after divorce are understudied, and most researchers who have considered fathers have studied nonresidential fathers.

There is strong, consistent correlational support for the protective effect of high-quality mother–child relationships. Mother–child relationships characterized by warmth, supportiveness, effective problem-solving skills, positive communication, and low levels of conflict and negativity are consistently associated with children's lower mental health problems and positive social adaptation outcomes, including higher self-esteem and better academic performance following divorce.

The results of experimental trials of preventive interventions have also shown that intervention-induced increases in mother–child relationship quality account for reductions in children's mental health problems. Because randomization to an experimental versus control condition makes it unlikely that third variables (e.g., shared genes, economic hardship) account for the relations between program-induced changes in relationship quality and changes in children's mental health problems, inferences about the causal nature of the relations between mother–child relationship quality and adjustment outcomes are strengthened over what can be inferred from correlational studies.

Correlational research has provided consistent support for the association between fewer postdivorce adjustment problems and use of effective discipline, which entails parents consistently enforcing age-appropriate rules, expectations, and rule compliance. Experimental trials of preventive interventions for divorced families have shown that program-induced improvements in mothers' use of effective discipline accounted for program effects on externalizing problems, delinquency, and academic performance.

Parental monitoring is an aspect of parenting that becomes especially relevant in adolescence given the normative increases in independence and time spent with peers. Correlational research has shown that adolescents whose mothers engage in higher levels of monitoring have lower levels of externalizing problems, substance use, and academic difficulties than those whose mothers engage in lower levels of monitoring. Experimental research with divorced families has shown that program-induced changes in parental monitoring accounted for program effects on adolescent substance use 6 years after participation for youths who had high levels of risk for developing adjustment problems at program entry.

Most of the research on the father's role in children's postdivorce adjustment has focused on whether the amount of father–child contact affects children's adjustment after divorce. Findings from this line of research have been inconclusive. Over the past couple of decades, researchers have used a more

fine-grained approach to identify aspects of postdivorce father–child relationships that matter for children's outcomes. Results of *meta*-analyses have shown that feelings of closeness; authoritative parenting, which entails a balance of encouraging children's independence and enforcing limits; and maintenance of appropriate expectations were significantly related to greater academic success and lower levels of externalizing problems and internalizing problems after divorce. Also, results of a *meta*-analysis that examined children's adjustment outcomes in sole- and joint-custody arrangements found that children in joint custody were better adjusted than those in sole custody and no less well adjusted than children living with married parents, supporting the importance of both parents remaining involved in parenting following divorce.

Most researchers have examined the relations between children's relationships with *either* mothers or fathers and children's postdivorce adjustment without considering their interplay. The few studies to examine the joint effects of parenting of mothers and fathers have shown that high-quality, responsive parenting by fathers *and* mothers was significantly related to lower mental health problems after accounting for the quality of the relationship with the other parent. Researchers who have compared adjustment outcomes of children who had a positive relationship with one parent, both parents, or neither parent have found that having a positive relationship with either the mother or father was associated with fewer mental health problems compared with not having a close relationship with either parent.

Child Factors

Researchers have examined whether age and gender predict postdivorce adjustment outcomes. Some studies, particularly older studies or those examining conduct problems, show greater adjustment problems for boys than girls. However, *meta*-analyses show that divorce was associated with adjustment problems for both boys and girls. Although *meta*-analyses show that children in middle childhood and adolescence appear to be more negatively impacted by divorce than preschoolers or college students, far fewer studies have examined postdivorce adjustment in these latter two age groups, making it difficult to draw firm conclusions regarding the relation between age at the time of divorce and children's adaptation.

There is a growing literature that shows that how children interpret and cope with divorce-related stressors affects their adjustment. Children who interpret divorce-related stressors in a characteristically negative style or as threatening to their well being have more postdivorce adjustment problems than children who interpret these stressors in a less negative manner. Coping efficacy, a global belief that one can deal both with the demands made and emotions aroused by a situation, has been shown to relate to lower postdivorce internalizing problems. Also, children who use active coping strategies, such as problem solving or positive cognitive restructuring, experience fewer mental health problems than those who employ avoidant coping strategies, such as disengaging from potentially stressful situations. The adaptive value of specific coping strategies depends on context. For example, children might benefit from using cognitive restructuring in situations that are largely outside of their control, whereas problem solving might be adaptive for situations that are more controllable.

There is also evidence that children's beliefs about social relatedness, self-worth, and control predict postdivorce adjustment problems. For example, concerns about social relatedness, defined as fear of abandonment, predict higher levels of mental health problems. Also, higher levels of self-worth relate to lower levels of mental health problems, and higher levels of internal locus of control predict lower levels of mental health problems.

Summary

Researchers have identified several potentially modifiable environmental-, family-, and child-level factors that are correlated with children's postdivorce adjustment outcomes. Although most research has examined direct relations between individual factors and children's outcomes, a few researchers have examined additive and interactive effects of some of these factors. For example, several researchers have shown that high-quality mother–child relationships reduce the negative impact of divorce-related stressors. At high levels of divorce stressors, children with higher quality relationships have fewer internalizing problems and externalizing problems than children with lower quality relationships.

Interventions to Reduce or Prevent Children's Postdivorce Adjustment Problems

Despite the high prevalence of divorce and large body of research demonstrating that parental divorce is associated with negative outcomes for many children, few rigorous trials of programs for divorced families have been conducted. Most of the programs that have been evaluated involved children only, some focused on parents only, and others included separate components for children and mothers. While most interventions have been developed and implemented in the United States, some programs have been implemented in several nations, such as the Children of Divorce Intervention Program (Pedro-Carroll and Cowen, 1985), which has been widely utilized in the United States, Canada, New Zealand, and Australia. The programs that have been found to have positive effects on children's adjustment outcomes have targeted factors that have been shown to be significantly related to children's postdivorce adjustment.

The most widely available preventive interventions are relatively brief (6–12 sessions), child-focused programs that are typically provided in school settings. Such interventions provide emotional support and teach adaptive coping and control beliefs. Several programs have been evaluated in experimental or quasiexperimental trials and have been shown to lead to improvements in multiple aspects of postdivorce adjustment outcomes, including internalizing problems, externalizing problems, self-concept, and competence. Program effects have been maintained 1–2 years after program completion.

Preventive programs that target primary residential parents have focused on teaching effective parenting skills to enhance the quality of parent–child relationships, increase the use of

effective discipline, and help parents reduce children's exposure to divorce-related stressors, such as interparental conflict. Experimental trials have shown such programs to have positive short-term effects on mental health outcomes and positive long-term effects on mental disorder, substance use disorder, frequency of alcohol, marijuana, and other drug use, delinquency, arrests, risky sexual behavior, academic performance, and self-esteem. Some research has shown positive program effects into young adulthood, and both short- and long-term improvements have been shown to be accounted for by intervention-induced improvements in mother–child relationship quality, effective discipline, and parental monitoring.

Programs that included components for parents and children were based on the premise that targeting empirically supported factors that are primarily controlled by children (e.g., coping) as well as those controlled by parents (e.g., effective discipline) would lead to additive effects. Surprisingly, research on dual-component programs involving mothers and children has *not* shown that more program components are better.

Summary

Several trials have shown that programs that targeted empirically supported family- or child-level factors improved multiple aspects of children's short- and long-term postdivorce adjustment outcomes. These findings have important public health implications given that their widespread implementation could significantly reduce the public health burden of parental divorce.

Conclusion

A sizable number of children, particularly in the United States and other developed countries, experience parental separation or divorce. Although most youths whose parents divorce do not have significant problems, a substantial minority are at increased risk for a variety of both short- and long-term problems. These problems include mental health, physical health, and substance use problems, lower educational and occupational achievement, and difficulties in interpersonal relationships. Research has identified potentially modifiable factors that are significantly correlated with postdivorce adjustment, such as parent–child relationship quality and coping efforts. Several interventions that target these factors have been evaluated in rigorous experimental trials and have been shown to improve children's postdivorce adjustment outcomes.

Abstract

This article examines the dynamics and forms of networks used in world shipping from the sixteenth century to the present day. It begins with a theoretical exposition of network structures, ethical standards, and internal functions in order to develop a basis for analyzing how these cooperative constructs were employed by British, European, American, and Japanese shipping enterprises. The article also explores the impact of technical and legal changes, especially the recent introduction of containerization, new shipbuilding methods, logistics, and computerization.

A network is an informal alliance of decision-makers (people or firms) that seek to further their mutual interests through cooperation. Networks are arguably the oldest of all frameworks used for organizing complex business activities. While other structures, such as partnerships and companies, are also of long lineage and widely employed, network-based constructs have persisted. They have been especially prevalent in certain industries, including shipping, merchant trading, finance, insurance, and more recently in film-making, raw material exploitation, engineering, and construction. In some sectors, networks proved to be of temporary relevance, especially in early developmental stages, and were superseded by other forms, usually the company. However, the network should not be considered as a transient business construct. Historically, it has proved to be a durable and distinctive structure (Powell, 1990). Moreover, in specific industries and historical contexts, it has been ubiquitous. Entrepreneurs from many countries have employed it, and indeed the network has been very evident in transnational business.

Broadly considered, there are three generic structures that can be used to effect economic exchanges. G.B. Richardson (1972) suggested that these constructs can be arranged along a spectrum, with the first, markets, and the second, hierarchy, positioned at opposite ends. In between these polar extremes, there resides an array of cooperative frameworks that generate varying levels of interdependence; they include long-term contracts, franchising agreements, joint ventures, strategic alliances, and the subject of this article, networks. Each of these three generic exchange-facilitating institutional frameworks possesses distinctive coordinating properties. At one end of Richardson's spectrum, market transactions are often depicted as supportive of one-off transactions between anonymous parties all of whom have complete information regarding considerations relevant to the exchange in question. Market forces of supply and demand generated by many such participants acting in a self-interested way to maximize their own private benefit determine the level of prices, which are the key bits of information upon which dealers act. At the other extreme, hierarchies (corporate or governmental) coordinate internal exchanges by means of commands issued by a legitimate authority residing at the apex of the structure. Information gathered and processed internally through various levels of the organization is the basis of decision-making. In contrast to both markets and hierarchies, exchanges within cooperative frameworks are shaped by the mutual interdependence of participants. In the short-term, these actors relinquish a measure of their freedom to follow the self-interest that actuates market dealers, in order to gain greater benefits through long-term cooperation. Within these frameworks there is no absolute authority that directs other members, as is the case in hierarchies, although there are often differentials in the power or influence among cooperators. For decision-making purposes, cooperative constructs rely on a mixture of interpersonal/organizational knowledge and preferential intelligence available only to members (see below). Networks share these basic characteristics of cooperative frameworks, but they exhibit their own distinctive properties.

Network interaction is based upon reciprocity; one member does another a favor on the expectation that it will be eventually returned. There is no preconceived time-frame for the payback, and the favor returned may not necessarily be precisely of equal benefit to the original one. Thus, reciprocity may or may not be symmetric. Over the long-term, however, the 'gives' and 'takes' are sufficiently equivalent to sustain enduring association. Underpinning reciprocity is trust, which is not reflective of a naive faith in others but rather what Mark Casson (1997) described as "a warranted belief that someone will honour their obligations, not merely because of material incentives, but out of moral commitment". Thus, network members possess sufficient interpersonal knowledge to judge the likely pattern of each other's future behavior. To these considerations we can add participants' recognition that an economic actor can be trusted because 'reputational deterrence' exists. The idea here is that trust in large measure arises as someone acquires a reputation for behaving in a consistently honorable way over a long period of time. Because renown is subject to rapid dissipation when one, who has hitherto been trustworthy, unexpectedly behaves opportunistically, with the consequence that future social and economic transacting possibilities may be severely curtailed, and may be difficult to recover, persons of high standing will be deterred from committing overt and guilefully self-interested acts. 'End game' strategies apart, participants infer that the greater the social, economic, and public capital an individual has accumulated, the more powerful the deterrent effect. Moreover, the reputations of members tend to become shared as a result of long-term affiliation and consistent behavior. For this reason, membership is exclusive. Participants need to safeguard their personal and collective interests from opportunists.

Alvesson and Lindkvist (1993) observed three broad types of network as determined by the nature of exclusive affiliation. First, 'economic cooperative' networks coordinate business activities alone and rely primarily upon mutual pecuniary gains to bind their members. Second, 'socially integrative' forms arise from some ethnic, religious, or cultural commonality among participants. Third, and perhaps the most basic, is the 'blood kinship' network which is founded on an extended family. Yet, in practice, networks often rely on combinations of family ties, common social/cultural affiliation, and shared business interests.

The significance of these bonds lies in their capacity to enhance particular forms of information exchange. As informal communicating systems, networks reduce uncertainty associated with transacting by conveying interpersonal knowledge that generates higher levels of trust than those prevailing in markets or hierarchies. In turn, trust sustains forthright communication that reduces transacting costs which arise from the necessity of building safeguards against being cheated. Thus, network members can quickly negotiate contracts, they can rely upon network connections and affiliation to confirm that the terms of the agreement are fulfilled, and they can depend upon noneconomic ties to provide a network 'culture' which by mobilizing feelings of inclusion deters opportunistic behavior.

With these strong foundations, network associates can share risks and assemble complex, growth-supporting sets of resources that one entrepreneur acting on their own might not be able to mobilize. The resource collection usually consists of capital and physical assets, but of greater significance it also includes preferential information and accumulated knowledge. Exchanges involving the latter two intangibles are notoriously problematic because it is difficult to determine a fair price without prior disclosure, and once information/knowledge has been revealed it can be used without paying compensation. Based on trust and expectations of reciprocity, networks have advantages in surmounting these problems and lowering the cost of making what otherwise might be prohibitively expensive transactions.

As trust-based communicating systems, networks preferentially circulate information that is 'thick' and 'rich', that is intelligence that has been preprocessed to some degree, is grounded in a context understood by each member, and enhanced by discussion. This type of valuable information contrasts starkly with the 'raw' publically available data that swirls around markets and is freely accessible by all economic actors. Unlike hierarchies where security concerns may limit the breadth of transmissions or cause content to be filtered, networks sustain 'free flowing' information that is complete and unfiltered. These reasons explain why networks are sometimes considered to be more flexible and dynamic than hierarchies. However, certain members of these cooperative constructs may occupy 'nodal' points within the web of communication channels and thereby have information-related advantages relative to other participants. Such figures derive power and what theorists call 'centrality' from their positions, and they are thus well placed to perform intermediary roles in distributing intelligence and arranging deals.

The nature of specific network channels also shape the quality of transmissions. A distinction is often drawn between 'weak' and 'strong' ties (Granovetter, 1973). The latter are based on common affiliation: members so joined observe shared routines that guide their interaction and engage in highly contextualized exchanges based on intimately shared experience that sustains a collective memory. Participants linked by strong ties know what each other know and can fairly accurately anticipate how one another will react to new stimuli. Thus, strong ties support rapid communicating and transacting as well as deep learning. They also muster a degree of anticipatory capability. In contrast, members connected by weak ties are not closely bound cognitively or in terms of shared experience. A weak tie arises when one member has an alternative set of information or a different way of processing intelligence perhaps because they come from a more distant social/culture background or have been educated in a particular way. As a result, these figures may furnish new data or singular analytical capacity, either of which may stimulate the recognition of new business opportunities. Network longevity is determined by many factors, but replenishing the constituent knowledge/information base by forging new weak ties is often important in generating enduring dynamism. Conversely, the collective memory enjoyed by participants bound by strong ties, being founded on common cognitive and behavioral conditioning, may create rigidity when completely new conditions arise within the external business environment. 'In grown' networks may fail to modify their processes or prove incapable of securing the new skills needed to adapt. All of these factors help to explain the rise and decline of specific maritime networks.

British Shipping

The discussion begins with British maritime networks, not because this cooperative structure originated in that country – indeed it arose in ancient times and was used by nearly every nation – but rather because Britain was the world's foremost shipping and trading nation for such an extended period and because the relevant literature is so well-developed. From the sixteenth and seventeenth centuries, British private overseas merchant trading businesses relied on blood kinship networks to support their activities and over time developed larger social integrative forms to secure resources from wider ranging religious, social/cultural, and geographically determined links. Moreover, despite their 'corporate' vestment, the great chartered companies – British, Dutch, and French – which enjoyed national monopolies in the geographically circumscribed trades, often employed networks of the economic cooperative form to harness the required resources and to control far flung operations. Before occupational specialization unfolded on a wide basis, freelance merchants and those associated with chartered entities traded and shipped goods. Both types of business worked across considerable distance and, without high-speed communication technology, firms in these sectors were compelled to delegate many functions to persons who had first hand information about conditions at points far from headquarters. As a result, personal knowledge, established bonds of trust, and participative incentives, all mobilized through network structures, were used to bind the interests of principal owners resident in the metropolis and ship masters, traders, and agents working abroad. In terms of resource

mobilization, even though a rich merchant could afford to buy a vessel independently, he attracted funds from allies in order to spread risk. (A reliable insurance market did not appear until 1771 when the principal supporters of Lloyds reformed its operation.) Uncertainty was pervasive: apart from the challenges of maintaining control, shipwreck, war, piracy, and unpredictable markets posed serious external threats. As communication systems, these early networks supplied information needed to reduce risks arising from internal sources and to assess the likely consequences of dangers posed from outside the venture. Finally, the network provided a mechanism for distributing residual and uncontrollable risk across its membership.

The traditional form of vessel ownership – the precise origins are not known – in which the capital invested in a ship was divided into 64 shares, allowed for significant risk spreading (Davis, 1962). The so-called 64-share system constituted a partnership in which investors, led by a managing owner (see below), were legally considered as tenants in common, and could sell or mortgage their shares without consulting other shareholders. Moreover, should an investor die, their shares passed to their estate and did not revert back to the partnership which continued to operate. (In contrast, land-based partnerships were dissolved if one member passed away, and individual partners could not mortgage or dispose of their shares without the agreement of all other owners.) Shipping came under the jurisdiction of Admiralty Law which deemed the vessel, not individual partners, as the responsible party, so that maritime investors enjoyed a limitation on their financial exposure. (The liability of landward partners was unlimited; each was responsible for debts incurred by the partnership and even other partners, to the full extent of their personal assets: 'to their last shilling and last acre'.) Individually the '64' owners (64thers) were only accountable for their share of any trading loss the vessel might sustain – profits were distributed in 64 proportions – and for their portion of any unpaid instalments due to shipbuilders. Thus, those who organized 64thers still had to attract solid and respectable investors, even though they faced less onerous internal risks than partners in land-bound business.

After the passage of the Bubble Act (1719), which severely restricted the formation of joint-stock companies, investment in shipping flowed through a legal loophole that made passive participation a relatively safe proposition. This interstice arose from recognition of the comparatively large capital requirements of ocean transport, the attendant risks, and its strategic importance. As a result, managing owners who could extend their networks and acquired sufficient renown had significant advantages over entrepreneurs in other sectors in attracting large amounts of capital from passive investors who came from a wide range of social, occupational, and geographic connections.

Within these larger constructs, ownership and management became somewhat separate, in part because occupational specialization grew from the late eighteenth into the early nineteenth centuries. Although the pace and extent varied, the increasing scale of markets supported larger enterprises, accentuated the generation of esoteric knowledge as well as skills which generated economies of scale in their application, and encouraged entrepreneurs to focus on a specific business activity. Gradually, general merchant shipowning traders concentrated on vessel management, trading operations, or finance. They often maintained portfolios of diverse interests and continued to reap economies of scope, but increasingly they directed their active endeavor toward a single business.

In shipping, managing owners, or managing agents, as they were often called, specialized in acquiring, outfitting, maintaining, and deploying vessels in trades in which they had some knowledge advantage. (Ship masters who accumulated sufficient funds also took up this occupation.) Increasingly, these figures managed ships that operated in a growing market for oceanic transport services. Their main interest was in carrying goods owned by others, although they sometimes arranged consignments of their own to load up their vessels.

The size and diversity of networks varied from port to port and changed across time, but most of them were configured according to the following representation. The 64er-based networks, as well as those that supported private joint-stock companies, chartered entities, and other ownership structures that emerged in the nineteenth century (see below), may be conceived of as a target consisting of three concentric circles which represent knowledge of diminishing quality as the distance from the bullseye increases. At the center, resided the managing agent who possessed superior information relative to other network investors, and it was this advantage that qualified him to occupy this key nodal position. His knowledge, track record, and reputation enabled him to contract with other investors who lacked first-hand knowledge of the venture's prospects and timely intelligence regarding its performance week to week or month by month.

The next circle, called 'the active core', included figures from some maritime-related occupation which provided them with the means of directly supporting the shipowning enterprise. Moreover, their decision to invest was informed by the specialized knowledge they accumulated in their main business and sustained by operating intelligence they gleaned through working directly with the managing agent. Thus, following the principle of reciprocity so important to network dynamics, sail makers, rope manufacturers, chandlers, provisioners, insurance brokers, and merchants committed funds on the expectation that their principal business would receive support from the managing agent's shipping venture, and in turn this working relationship provided them with some impression of its performance in addition to the data included in voyage reports issued by the managing agent. (For example, an insurance agent obtained some idea of the quality of the master and the extent to which a vessel was properly maintained from the quotes he received for coverage and by subsequently monitoring the frequency and nature of claims.) The geographic proximity of the managing agent might also give active members impressions of his reputation, his personal and business circumstances, and any wider associations he might have. A ship master bought or earned 64ths that served respectively as a bond or an incentive, and his reputation for safe navigation and prudent dealings at distant ports conveyed important impressions to other investors. (Indeed, so significant was the master as a factor determining risk, that Lloyd's compiled a register that recorded their performance to inform brokers' rate quoting decisions.) If the venture involved a new

vessel, its builder usually became the most important active constituent in the supporting networks. He had preferential information relative to all other members, including the managing agent, regarding the quality of the vessel's construction and thus his investment in 64ths represented a form of bond or guarantee. (So close and enduring did shipowner–shipbuilder links become in the steamship age that shared cognitive frames developed to facilitate their ongoing transactions (Boyce, 2003).) Often, builders took up sizable holdings which signaled their confidence to all other network constituents, and these men were well-known and highly respected in their port communities. Securing the support of a prominent shipbuilder was often the first step in the managing agent's network building endeavor for it brought reputation-by-association, which was subsequently enhanced as other active participants joined in.

When an 'active core' possessed substantial collective stature, it was relatively easy to attract a 'passive fringe' of rentier-type investors. These members possessed comparatively low quality information to guide their fund allocation activities, since they usually had no connection with a maritime business through which they could obtain impressions of prospects and performance. Instead, they relied on family or social ties with an active constituent, reputational assessment of the managing owner and his allies, and local knowledge. They monitored a venture over time with the aid the accounts that managing agents circulated at the end of each voyage and informal communication with he or other key members. Those included in the 'passive fringe' often consisted of wealthy farmers, local manufacturers of non-marine products, professionals, women, and the ubiquitous 'gentleman'. Shipping networks exhibiting this basic architecture proliferated and endured through the nineteenth century and into the twentieth because they furnished an effective framework for arranging contracts based on knowledge.

A Networked World

Between 1850 and 1914, world trade grew rapidly and production became more specialized geographically as a result of the spread of liberal trading policies, monetary stability based on the gold standard, population growth, the installation of a worldwide telegraph network, and the increasing mechanization of land – and sea-ward transportation systems. By the end of this period, 'the first global economy' had matured. Michael Miller (2012) argued that worldwide trading and shipping operations became enveloped in three networks centered on major European ports. First, hinterland connections radiated outward from the major ports of Britain and continental Europe. These links collected manufactured goods for export to developing regions and distributing primary products imported from colonies and areas of recent settlement. Second, merchant enterprise created global webs that organized the flow of commodities, consumer goods, and capital equipment, and in many instances these businesses played important roles in funnelling investment funds to productive opportunities overseas (also see Jones, 2000). Finally, shipowners, especially those operating liner services, created the oceanic transport systems needed to move people and goods around the globe. The economic structures that operated within these three sets of connections were network-based: port communities were interlaced with informal links, merchant enterprises were web-like cooperative constructs, and, of course, merchant shipping relied on its traditional information and resource gathering frameworks that became larger and increasingly complex.

The operation of these three interrelated systems was conditioned by the same commercial culture. This has been termed 'gentlemanly capitalism' and it grew from the transference of aristocratic patterns of behavior and standards of conduct to the business arena as a result of increasingly intimate interactions between members of the British ruling elite and commercial interests, especially bankers and financiers (Cain and Hopkins, 1993a,b). It was based on traditional conceptions of trust and honor, a common understanding of fairness and compromise, and recognition of mutual interdependence. As social and economic mobility unfolded over time, new occupational groups, including first merchants, then shipowners and others linked to maritime endeavor, and later yet major industrialists, came to observe the basic tenets of gentlemanly capitalism. Moreover, maritime entrepreneurs around the world followed suit. Although Miller detected the concurrent operation of other perspectives and mind sets at work, gentlemanly capitalism provided a central and vital cultural foundation for arranging complex transactions across the first global economy.

Gentlemanly capitalism also shaped behavior in exchange facilitating ways across the commercial infrastructure that sustained maritime business. A series of major business centers arose across Europe – Hamburg, Antwerp, Rotterdam, and lesser ones like Le Havre and Marseilles – but London emerged as the largest and most important of all. Its rise as the center of world trade, finance, and insurance was tied to the growth of specialized markets for goods and services. London became a veritable emporium where traders in specific commodities gathered first in seventeenth century coffee houses and then later in grand purpose-built venues to make transactions. The origins of the London Metal Exchange can be traced to the Jerusalem coffee house, the Virginia and Maryland coffee house provided the foundation for the Baltic Exchange, the world's center for commodity trading and ship hiring, and most famous of all Edward Lloyd's establishment in Tower St. developed into Lloyd's of London where insurance coverage was arranged across the globe. London hosted the Royal Exchange, the Stock Exchange, and a plethora of specialist commodity markets that set prices and standards for worldwide trade. Within these transacting arenas, networks also arose as individuals gained sound reputations and attracted allied dealers (Boyce, 2012). Norms and ethical standards associated with gentlemanly capitalism found expression in the motto of the Baltic Exchange, "our word is our bond" and that of Lloyds 'sine praejudicio' (without prejudice). Aided by this ethos, these markets working in combination constituted a vital commercial infrastructure for worldwide trading and shipping enterprise and the efficacy of this cultural edifice is reflected in the role it played in helping to sustain maritime networks during a prolonged period of salient technological and legal change.

Changes in Technology, Legal Regulations, and Organization

Adam Kirkaldy (1914) argued that the application of steam power to merchant shipping, a process in which Britain led the way, unfolded at a gradual pace between 1820 and 1890, but it induced fundamental changes in legal and financial structures within the sector. Steam propulsion made it possible to form liner services that involved regular calls at specified ports according to a fixed timetable. To run this type of business, shipowners had to make major investments in fleets of expensive vessels suited to cargo flows generated from the individual ports they visited. In addition, they had to develop complex support services. As a result, fixed costs increased significantly, and these businesses sought to attract high value general cargo that could sustain high freight rates through fast and reliable service. (High valued general cargo imposed onerous inventory costs upon merchants who were thus willing to pay more for its transport.) Kirkaldy observed that Britain's subsidized mail and passenger lines which appeared between 1830 and 1850 employed the joint-stock company and later became limited liability firms following the passage of general incorporation laws between 1855 and 1862. After 1860, private partnerships also shifted to limited liability enterprises to support liner operations. In the tramping sector, based on the carriage of full loads of low value bulk commodities between any ports nominated by merchants, single-ship limited firms appeared in large numbers and, in the 1870s, precipitated a speculative frenzy supported by investors from low and middling occupations. Yet, long-standing reputable shipowners retained the 64th system for several decades, in part because they and their allies believed that it conveyed valuable signals of personal commitment and probity. Moreover, contrary to Kirkaldy's assessment, these technical, legal, and operational developments did not undermine the traditional network foundations of maritime enterprise in Britain and continental Europe.

The early subsidized liner enterprises were formed by bands of allies, well known to each other, who pooled the required capital, physical assets, and business connections; most can be classified as economic cooperative networks that sustained subsequent growth by attracting a passive fringe of investors. Privately supported limited liability liner firms were configured so that the control of managing agents' families was consolidated and included active participants within a large social-integrative construct. Over time, these enterprises brought in outside rentier investors usually by offering them securities with restricted voting rights. In neither case did ownership and management become decisively divorced and administrative tasks did not require the creation of hierarchies. Within tramping, blood kinship and social integrative networks persisted and, like the liner firms, they developed passive fringes. (Traditional 64th managers, like Walter Runciman and James Knott, often developed close relations with nonactive participants; what nowadays is called 'investor relations' were almost intimate in these cases.) In both parts of the industry providers of support services were included in network cores, giving them an economic cooperative flavor, but social ties provided their real foundation. Principals and agents apprenticed each others' sons and nephews, and marriage ties often furnished additional adhesion. Network dynamics, norms, and cognitive frames extended across a wider group of allies beneath the surface of new legal forms which were manipulated to preserve private control (Boyce, 1992).

After the shipping cycle peaked at abnormally high levels in 1900–01 as a result of the Boer War combined with a surge in world trade, changed environmental conditions again caused network adjustment. A prolonged recession (1902–11), increasing foreign competition, and the consolidation of the conference system (a form of economic cooperative network that liner firms used to contain competition) lay behind this development. Most tramp owners continued building up their fleets and many consolidated their single ship firms into a limited liability company, but they still relied mainly on home port networks. However, a few did establish offices in London to tap into the capital's dense webs of information and other key ports from which they drew custom. The main liner operators enlarged their local networks by allying with figures of wider geographic and occupational affiliation. Lord Inverclyde (Cunard) and Lord Inchcape (P&O) established ties with government, while shipowners who exploited new specialist trades (fruit, oil, and refrigerated meat carrying) built new links with cargo suppliers and distributors. Investment bonds appeared between shipping and shipbuilding, steel, engineering, and coal firms – those formed by Sir Christopher Furness (later Lord Furness) around 1900 being the most noteworthy – and some large shipbuilders, especially Harland and Wolff, established close long-term contractual ties with their clients. In these ways, the extent and nature of network linkages shifted to secure access to new sources of information and emerging bases of specialized knowledge needed to sustain growth.

After world trade revived strongly in 1911, the structure of British shipping changed again as five major corporate groupings appeared. These enterprises – the so-called Big Five: Cunard, P&O, Furness Withy, Ellerman, and the Royal Mail – were built on the holding company structure, consisting of one or more parent entities that controlled and sometimes managed stables of subsidiary shipping, industrial, and service units. This development was supported by high profits and encouraged by the increased availability of acquisition targets as the first generation of steamship entrepreneurs retired or passed away. Growth by take-over continued during the World War I as u-boat losses, constrained access to shipbuilding berths and Excess Profit Duties encouraged acquisitions of shipping firms to secure tonnage and widespread backward extension of ownership ties with heavy industry. The big groups became interorganizational networks in which parent company nodes occupied positions of increased centrality relative to growing numbers newly acquired subsidiaries. For each of the Big Five, take-over patterns usually followed previously established communication lines and channels of interpersonal knowledge. Both defensive and offensive considerations propelled growth. Thus, crises in managerial succession exposed long-standing interfirm links which dominant firms safeguarded by acquiring the faltering firm, while other companies with valuable goodwill, knowledge, and contacts attracted bids from the majors. To fund these acquisitions, the main groups employed outside finance, especially debt, on a much larger scale and their leaders, all

men of growing economic and social stature, built stronger links with banks. Yet, the great shipowners juggled financial obligations with a widening array of capital suppliers in ways that preserved their control and freedom of action. As a result, underlying network structures remained intact: Some groups, like Cunard were sustained by interfamily ties of the social integrative type, while others were controlled by a single family and developed features of the economic cooperative network.

The Emergence of New Challengers and the Decline of British Maritime Networks

On the eve of the World War I, British shipowners commanded about 40% of the world's merchant fleet (Sturmey, 1962). Other countries attained less formidable but still significant positions in the industry with the aid of network structures. However, most other nations lacked the huge reserves of family-based wealth needed to found purely blood kinship networks and therefore relied on other economic agents to assist growth.

In Germany, the second largest shipping nation by 1914, merchants and other members of port communities worked together to pioneer steam services. After 1900, the great German lines, HAPAG and Norddeutscher Lloyd, forged supporting alliances with industry, government, and major banks. In contrast, Woerman, who was a specialist operator continued to rely on merchant links to build his business. Government aid in a variety of forms was vital to the expansion of Japan's merchant navy which ranked third in the world (Davies, 2008). The United States had built up a position as the foremost shipping country in the age of sail with the support of port-centered family networks, but after the Civil War these constructs had been destabilized by social and cultural turbulence and by a shift in business opportunity in favor of landward pursuits with the development of the West. America was a minor player before 1914 because it lacked any comparative advantage in steam shipping, and the few enterprises that arose in the oceanic transport sector were developed by corporate groupings consisting of railroads and banks. At the turn of the century, J.P. Morgan attempted to push the US to the forefront by merging several leading British and American lines under the banner of the International Mercantile Marine Corporation and aligning this new entity with German and Dutch shipping firms as well as Belfast shipbuilder Harland & Wolff. However, the combine was overcapitalized and struggled to earn sufficient profits with the result that it fell apart after World War I. In contrast, Greek, Spanish, and Scandinavian shipping employed family and social/cultural networks to build up their merchant navies before 1914.

World War I disrupted established shipping routes and changed patterns of world trade. America and Japan emerged as more important focal points of international commerce, while Russia largely withdrew from the world economy. Debate has developed as to whether the global economy that existed before 1914 retreated in the interwar period, or whether the internationalization of activity continued but in different directions, geographically and in terms of commodity trades. Brink Lindsey (2001) argued in favor of retreat whereas Michael Miller (2012) supported the view that ongoing development occurred but in new forms. It is true that the transatlantic passenger business declined when the US began restricting immigration, but streams of migrants from Eastern Europe and from within Asia arose to create new demand. Some long-established cargo liner routes declined or stagnated but new opportunities arose after the opening of the Panama Canal and some expanding South American trades provided increased employment for shipping. Britain's coal exports declined as new sources of supply emerged and as oil became an increasingly important substitute fuel. These developments reduced the volume of outbound cargoes for tramp ships leaving Europe and deprived many of two-way trading opportunities.

Adjustment to these shifting conditions was hindered by persistent worldwide oversupply of shipping capacity in relation to the volume of goods requiring transport. Despite enormous war losses, between 1913 and 1920 the global fleet grew by about 25% to 51.6 million GRT, as American shipyards, in particular ramped up production during the conflict. By 1939, it had reached 65.6 million GRT. Meanwhile, by 1924 the volume of seaborne trade returned to its prewar level and continued growing until it fell heavily in 1929 with the onset of the Great Depression. By 1939, trade has regained the level attained in 1929. Excess capacity dogged the industry even though the British, Japanese, French, and German governments introduced scrap and build subsidies to reduce the supply of obsolete tonnage.

Nevertheless, the period witnessed important shifts in the composition of the world fleet. Germany displayed remarkable resilience by reconstructing its trading networks after the nearly complete destruction of its merchant navy during the war. Japan made enormous strides as family-owned companies took advantage of government support and help from trading companies, industrial enterprises, and financial institutions affiliated with the Zaibatsu (family-controlled holding companies which resembled a cross between all three network forms identified by Alvesson and Lindkvist (Davies, 2008)). From this institutional foundation, Japanese shipping developed new routes and broke into European dominated conferences on a wider scale. Greek shipowners also reformed their networks and penetrated a larger range of deep sea tramping trades. Norway also enlarged its tramping business and became a major force in tanker operations. By 1939, the British fleet was still the world's largest but it had declined absolutely and relatively, accounting for 27.3% of the total. America came second with 13.6% but much of its shipping was government-owned surplus tonnage held in strategic reserve. Japan ranked third (8.5%), followed by Norway (7.3%), Germany (6.9%), and Italy (5.2%).

World War II witnessed further massive tonnage losses. After 1945, Britain's fleet ranked second in the world at 18 million GRT, behind a greatly expanded US merchant navy, which though it totaled nearly 41 million GRT, or 56% of the world total, was largely sold off to private owners and mothballed as a strategic reserve. The German, Japanese, and Greek fleets were virtually destroyed, while Norway's was reduced by half.

World trade underwent profound changes in the postwar era. With the reconstruction of Japan and Europe, a new form of globalization appeared. Decolonization broke apart the

Europe-centered routes which had previously connected dependencies with the main imperial nations. Increasingly, global exchange was concentrated between three main blocs: the US Europe, and east and South Asia. These key areas had subsidiary connections to South America, Africa, and Australasia. However, the extent to which the world was enveloped within a uniform 'global' system of exchange is subject to debate. Rugman (2003) argued that most investment and trade has been focused on pairs of the three main cores rather than embracing all of these areas of concentration and their satellite networks. Nevertheless, the nature and form of connectedness across the world changed significantly, and several factors played key roles in precipitating the shift.

Fundamental technical and institutional developments unfolded concurrently. First, vessel size increased to unforeseeable proportions as economies of scale were exposed by new modular construction techniques, more efficient propulsion systems, and a steep rise in the volume of goods requiring transport. These dynamics affected the tanker sector first, with particular poignancy when the Suez Canal was closed in 1956 and again in 1967, and then spread to the bulk trades where new ship designs eroded the market for traditional tramping services. Giant tankers and bulkers carried oil, iron ore, coal, and other basic commodities over greater distances, in larger quantities, and at lower unit cost than ever before. Other large specialized vessels appeared especially liquefied natural gas (LNG) ships, chemical transports, and car carriers. The passenger trades disappeared by the mid-1970s as jet aircraft of progressively greater size took to the air, but after a lag, the cruising industry blossomed and propelled by scale effects built large numbers of palatial ships of great size.

The general cargo or liner sector was completely transformed by containerization and the application of computer technology. Here to, the pursuit of economies of scale was paramount and their extent was accentuated by rapid growth in high-value manufactured goods that had been the preserve of the traditional cargo liners. Shipping items in boxes also transformed ports as facilities in city centers could no longer accommodate the huge volume of shipments being delivered and mustered for loading. Quays, storage yards, and craneage appeared at river mouths and new coastal sites that could accommodate massive container ships. Liverpool and London, both traditional centers of the general cargo trade, declined but other, long-established ports, like Rotterdam, adapted. New global container hubs appeared in what were previously secondary centers such as Hong Kong, Oakland, and Singapore. Containerization spawned intermodal transport that combined sea, road, and rail carriage with the aid of computer tracking and the application of logistics.

Institutionally, free trade policies promulgated by international organizations and supported by intercountry agreements encouraged rapid growth in global exchange. The deregulation of investment also spurred wider economic development. While flags of convenience had been exploited previously, they came into much wider use after 1945. Greek and American operators especially took advantage of the lower crewing costs and lax regulatory prescriptions these devices brought. All of these developments made national identity problematic within the new globalizing context.

Together, these changes challenged traditional maritime networks and created openings for new cooperative structures led by entrepreneurs from different backgrounds. Greece's long-standing island-based alliances were confronted by newcomers who rapidly built up large enterprises. In the tanker sector, Aristotle Onassis and Stavros Niarchos forged interorganizational connections with shipyards, financial institutions, and customers to achieve astonishing rates of growth. Firms that had been minor entities quickly achieved prominence in specialized sectors, for example the chemical carrying business run by Odfjells (Norway). Newcomers like Ted Arison and Sammy Ofer helped to transform cruising, while containerization was driven by men, like Malcolm McLean and Bruce Seaton, who came from outside the shipping industry. Denmark's major firms built conglomerate ties, and Norwegian owners formed long-term financial and chartering contracts to expand their businesses. The Japanese reconfigured their zaibatsu ties into vertically aligned keiretsu and pursued dynamic growth strategies through these interorganizational links. Entrants from South Korea, Taiwan, Singapore, and Hong Kong also created large networked enterprises. Despite their origins and principal operating bases, these entrepreneurs created multilateral affiliations that can be described as global rather than merely national.

Meanwhile, traditional liner firms quickly responded to containerization by forming national consortia, or economic cooperative networks to harness the resources needed to build the expensive fleets required in the new operating environment. However, these constructs were overwhelmed by the pace of change and replaced by international groupings. From the 1960s, network ties exhibited forms and a supporting culture that differed markedly from those that had previously sustained traditional European maritime endeavor. Now, competitive vigor was more overt (the decline of the conference system was symptomatic of a new dynamic), new skills based on computerized logistics became paramount, a university education assumed greater value than the old style on-the job and in-the-firm training processes, and the relevance of interpersonal relations and face-to-face contact declined. The networked basis of maritime business did not disappear, but it was utterly transformed.

Britain's shipping industry entered a period of precipitous decline in the 1970s. The private foundations of the sector had been undermined by an onerous postwar income tax regime, punitive inheritance levies, and new laws that destabilized privately owned companies. Labor governments had nationalized related industries – coal, steel, and shipbuilding – that had hitherto assisted shipping. New labor regulations hurt productivity and sapped investor confidence. Decolonization and the spread of discriminating legislation by the new governments of former colonies destroyed some of Britain's long-standing routes and dislocated the old trading companies that had worked in tandem with national vessel operators. Most fundamental, perhaps, were social and cultural changes that eroded the traditional culture upon which the maritime networks depended. As the relevance of gentlemanly capitalism receded, British shipowners found it increasingly difficult to extend their networks by forming new weak links that could have brought the new skills and information needed to exploit new opportunities.

Long-standing communication channels withered and patterns of socialization that had sustained family business and networking activities were confounded. Many aging industry leaders were discouraged and demoralized by changes unfolding from within the business arena and from the external environment (Boyce, 2010). Younger men from different educational and national backgrounds configured new cooperative constructs to exploit emerging opportunities.

Markedness in Linguistics

Edwin Battistella, Southern Oregon University, Ashland, OR, USA

Abstract

Originating in the Prague School structuralism of Roman Jakobson and Nikolai Trubetzkoy, the concept of markedness – asymmetry in linguistic structure – was proposed as a means of characterizing binary oppositions in phonology and soon after in grammar, meaning, and culture.

Today, markedness ranges over a variety of formal and typological senses and applications, but is not without those who question the coherence of the term.

'Markedness' refers to an asymmetry relation between elements of linguistic or conceptual structure. In a marked–unmarked relation, one term of an opposition or of a set is taken to be the dominant one while the other(s) is taken to be secondary. The dominant term is known as the unmarked term and the secondary one(s) is marked. Linguistic markedness ranges over phonological, grammatical, and semantic oppositions and constructions. The concept has been extended to the analysis of cultural relationships as well, with background or matrix cultural categories (right-handedness, sightedness, etc.) being taken as unmarked.

Background in the Prague School

As Henning Andersen (1989) has noted, the idea of asymmetry in linguistics predated the actual coining of the terms 'marked' and 'unmarked' in the 1930s, going back to work in the early 1800s. The modern concept of markedness originated in the Prague School structuralism of Roman Jakobson and Nikolai Trubetzkoy, and was proposed as a means of characterizing binary oppositions. In Prague School structuralism, both sound and meaning were analyzed into systems of binary distinctive features representing sound and meaning as the presence or absence of relational properties or features. Binarism suggests symmetry and equivalence in linguistic analysis; markedness added to that the idea of hierarchy and value. The fact that distinctions were characterized as the presence versus the absence of some property implied an evaluation of any opposition into a mark and its absence. Thus, for example, phonological oppositions such as nasal versus nonnasal were defined as the presence versus the absence of nasality; nasality was marked, nonnasality unmarked. Grammatical oppositions such as singular versus plural were defined as the presence versus absence of plurality.

Oppositions manifest asymmetry in several ways, most notably for Trubetzkoy in terms of the diagnostic of neutralization, whereby the unmarked term of a phonological opposition was thought to be that which occurred in positions where the contrast was neutralized (that is, where only one term of the opposition could occur). In his 1932 article "Structure of the Russian verb," Jakobson extended the concept of asymmetry to a view of grammatical meaning in which the marked element 'announces the existence of [some meaning] A' while the unmarked element 'does not announce the existence of A, i.e., does not state whether A is present or not.' This meant that an opposition like past versus nonpast characterized three interpretations: past, present (as the opposite of past), and timelessness (the neutralization of the tense opposition). More generally, any semantic opposition involved three meanings: two unmarked and one marked. Thus, old can refer to the opposition of young or it can refer to age itself, as in "How old are you?" (="What is your age?").

The breadth of the unmarked terms was extended by Jakobson to oppositions that were not inherently binary. In a 1972 article, Jakobson described language by saying "every single constituent of a linguistic system is built on an opposition of two logical contradictories: the presence of an attribute ('markedness') in contraposition to its absence ('unmarkedness')." Jakobson also suggested a role for markedness in language acquisition and loss, in his 1941 monograph *Child Language, Aphasia, and Universals of Language*. There Jakobson proposed a relationship between a universal feature hierarchy, the acquisition of sound distinctions by children and the loss of sound distinctions during aphasia. Today few linguists or aphasiologists would adopt Jakobson's positions literally, though many view them as useful tendencies (see Caramazza and Zurif, 1978).

Semiotically oriented work in the Prague School tradition has often viewed markedness as a means to investigate the isomorphism of form and meaning. Henning Andersen and Michael Shapiro, for example, have fruitfully linked markedness to semiotic universals and to the work of Charles S. Peirce. The work of Cornelius van Schooneveld, Edna Andrews, Rodney Sangster, Yishai Tobin, and others had foregrounded the notion of 'semantic invariance' (understood as the different general meanings reflected in the contextual specific meanings of features). The most well-known semantic invariants are those in Jakobson's analysis of the Russian case and verbs systems which attempt to ground semantics in spatial relations and in the relations among participants in the overall speech event (for recent work on invariance, see Waugh and Rudy, 1991).

Typological Universals

Markedness has also been applied to typological and functional approaches to language, influenced by Joseph Greenberg's 1966 book *Language Universals*. Greenberg surveyed the

correlates and diagnostics of markedness proposed by Jakobson, Trubetzkoy, and others in an attempt to find parallel diagnostic criteria across levels of language. Noting that unmarked grammatical categories in a language show characteristics correlated to the greater frequency of a category vis-à-vis its opposite, Greenberg took frequency to be the primary determining factor of markedness in grammar and suggested that unmarked categories could be determined by 'the frequency of association of things in the real world.' In addition to emphasizing the role of frequency in determining markedness within a language, Greenberg applied frequency cross-linguistically, taking unmarked categories to be those that are unmarked in a wide number of languages. However, while frequency is an appealing diagnostic, it is also problematic because a phenomenon may be infrequent cross-linguistically but predominant in a particular language (a much-used example is preposition stranding in English, which appears to be marked cross-linguistically but unmarked in English). See Pustet (2009) for an attempt to revisit the criterion of frequency and to explain markedness in terms of Zipf's Laws.

Universals have also been proposed on the basis of implicational laws, with a category taken as generally marked if every language that has the marked category also has the unmarked one but not vice versa. Other approaches to universal markedness relations focus on functional economic and iconic motivations, tying recurring asymmetries to properties of communication channels and communication events. Croft (1990), for example, notes that asymmetries among linguistic elements may be explainable in terms of economy of form, in terms of iconism between the structure of language and conceptualization of the world.

Comrie (1983) treats markedness in terms of human interaction with others and with the world rather than as a purely formal property of language. Similarly, Givón (1990) suggests that markedness is related to cognitive complexity – 'in terms of attention, mental effort, or processing time.' Mayerthaler, Dressler, and other 'naturalists' view markedness relations in terms of the ways in which extralinguistic principles of perceptibility and psychological efficiency determine what is natural in language. Mayerthaler (1988), for example, defines unmarked as "in agreement with the typical attributes of the speaker." In other words, 'up' and 'front' are unmarked concepts because we perceive thing in terms of growing up and looking frontward, rather than the opposites (see also Bybee, 2010).

Markedness in Generative Grammar

Markedness entered generative linguistic theory through Chomsky and Halle's *The Sound Pattern of English*. Following the Prague School view, phonological features were assumed to be part of a universal phonetic vocabulary. In addition, features were also incorporated into what was known as the 'evaluation metric,' a central concept in early versions of generative grammar. The evaluation metric was a means of selecting the most highly valued grammar capable of describing the facts of a language. In *The Sound Pattern of English*, the value of a grammar was the inverse of the number of features required in that grammar. However, Chomsky and Halle realized that their initial approach to phonological features made implausible rules and segment inventories as highly valued as natural ones. To deal with this, they introduced markedness as a means of encoding the intrinsic content of features. Chomsky and Halle proposed a set of 39 universal marking conventions, tying naturalness to evaluation. In their system, the unmarked value of a feature was cost-free with respect to the evaluation metric, while the marked values were counted by the metric. Segment inventories could also be evaluated according to the number of marked features required to characterize them; sets of lexical items could be evaluated for markedness based on the number of marked features they entailed; and a concept of 'linking' reduced the number of features required to characterize processes corresponding to the markedness conventions. However, the use of phonological markedness as part of the evaluation metric was never able to fully account for the fact that some features are more likely than others or for the fact that phonological systems must have a certain minimal complexity and symmetry (see Kean, 1980 for an early extension of the featural markedness theory to address these issues).

In syntax, markedness as feature-evaluation did not receive the same attention that it did in phonology. In Chomsky's work, markedness evolved to a view of unmarked properties as an innate preference structure based first in constraints and later in parameters of universal grammar. Beginning in the l970s, Chomsky attempted to greatly restrict the class of possible grammars, suggesting a relative rather than an absolute interpretation of conditions on rules. In such an approach, rules apply in accordance with the conditions unless specifically complicated to evade them, with Chomsky noting in his article "On Wh-movement" that "The logic of this approach is essentially that of the theory of markedness." In their 1977 article "Filters and control," Chomsky and Howard Lasnik extended this to view markedness as part of a theory of 'core grammar':

> We will assume that [Universal Grammar] in not an 'undifferentiated' system, but rather incorporates something analogous to a 'theory of markedness'. Specifically, there is a theory of core grammar with highly restricted options, limited expressive power, and a few parameters. Systems that fall within core grammar constitute 'the unmarked case'; we may think of them as optimal in terms of the evaluation metric. An actual language is determined by fixing the parameters of core grammar and then adding rules or conditions, using much richer resources, … These added properties of grammars we may think of as the syntactic analogue of irregular verbs.
>
> 430

What is unmarked is the entire core grammar of a language, which is then supplemented by a marked periphery. In later versions of his theories, Chomsky has explored various positions on markedness, for example, associating the unmarked with a child's initial hypothesis. In a 1986 work, he summarized his view as follows:

> The distinction between core and periphery leaves us with three notions of markedness: core versus periphery, internal to the core, and internal to the periphery. The second has to do with the way parameters are set in the absence of evidence. As for the third, there

> are, no doubt, significant regularities even in departures from the core principles (for example, in irregular verb morphology in English), and it may be that peripheral constructions are related to the core in systematic ways, say by relaxing certain conditions of core grammar.

Other researchers in generative syntax have tried to flesh out aspects of markedness, attempting to operationalize the idea of the cost of a marked syntactic construction or integrate markedness into the theory of parameters. Various approaches have been suggested, including tying markedness to an ordering of parameter values defined by subset relations among sentences, connecting it to types of triggering experiences or to default learning strategies, and using markedness to establish a universal syntactic feature hierarchy. Optimality theory (OT) approaches emerging in the 1990s also incorporate markedness. In such approaches, the surface forms of language arise from the interaction between conflicting constraints as underlying representations are mapped to outputs. OT models encode markedness in the constraints and their ranking (see Woolford, 2007).

Phonological Markedness in OT

OT has also reenergized the study of markedness in phonology. Paul Smolensky, one of the founders, characterized markedness this way in his article "Harmonic completeness, local conjunction, and feature domains":

> The working hypothesis is that 'less marked' can be formalized in OT as **more harmonic** according to markedness constraints, and that universal markedness relationships such as '[−φ] is less marked than [+φ]' are encoded in UG via universally fixed rankings.
>
> 2006: 36

Smolensky notes too that "Less marked elements are less active" in terms of phonological processes though he notes that this is 'far from a crisp result' (37). Initially, the markedness constraints of OT assigned violation-marks to output candidates in isolation – without reference to the input or to other candidate outputs. John McCarthy (2003) proposed an alternative, more global approach in which markedness constraints compare the candidate under evaluation with another candidate, the one most faithful to the constraints: a candidate output might thus contain a marked structure also present in the fully faithful candidate or it might contain a marked structure not present in that candidate output, and the two approaches yield different constellations of results. Paul de Lacy (2002, 2006) has explored how segmental, sonority, and tonal hierarchies combine with prosodic structures to constrain phonological outputs and has proposed that the markedness constraints fall into two semi-antagonistic sets: one that seeks to eliminate marked elements in the hierarchy and one that seeks to preserve them. These antagonistic sets interact to produce varying markedness in different situations: asymmetries in place neutralization, assimilation, deletion, coalescence, and vowel reduction.

Rice (2007) argues "Natural markedness criteria including language-particular and cross-linguistic frequency, ease of articulation, perceptual salience, and likely historical and social factors as well work together to determine the tendencies toward certain phonetic outputs" (96). She offers a critique of the diagnostic of neutralization arguing instead for a more refined view of the neutralization, epenthesis, together with situations in which marked features are preserved (such as some types of assimilation), which together can help to account for cross-linguistic variation. She writes "While two languages with identical surface contrasts within a class may differ in how they pattern with respect to submergence-of-the-unmarked diagnostics, this variation is not without limit: it is constrained, with only certain features demonstrating unmarked patterning in a given set of contrasts" (2007: 93). And in a somewhat different approach Elizabeth Hume (2005, 2011) has argued that the basis of phonological markedness lies in the cognitive process of expectation, quantified probabilistically. Expectation is defined according to the linguistic and/or extralinguistic context of a pattern and is tied to the individual speaker. Hume's approach thus reverses the usual approach of deducing markedness from universals to predict both individual and cross-linguistic markedness from the patterns up.

Second Language Acquisition

Some researchers – both generative and typological – have applied markedness to second language acquisition theory, treating it as an inherent learning hierarchy which reflects the sequence in which constructions are acquired, the difficulty of acquiring certain constructions, and the transferability of rules across languages (see Rutherford, 1982 for an early survey). As Gregg (1993) points out, in order for markedness to be useful as a potential explanation of second language (L2) acquisition, "it is necessary to define markedness in such a way as to connect it with learning mechanisms within the individual learner." Fred Eckman (2004) has proposed that markedness plays an especially crucial role in L2 phenomena which cannot be explained in terms of either transfer from the learner's native language or in terms of target language (his example involves the occurrence of resumptive pronouns in the relative clauses of learners of Swedish as an L2 which can be explained in terms of the Accessibilty Hierarchy proposed by Keenan and Comrie (1977); for a phonological example, see Ellen Broselow et al. (1998).

Markedness and Code Switching

Carol Myers-Scotton (1983, 1993) has suggested a markedness model of variation in linguistic code choices – code switching. The premise is that participants in conversation understand all code choices as unmarked or marked in reference to the norms of their speech community (1983: 115). She proposed that speakers choose forms to index "the set of rights and obligations which [they] wish to be in force between speaker and addressee for the current exchange" (1993: 113). The unmarked choice of form is associated with the social norms while marked language constitutes a speaker's negotiation for a different social norm. Myers-Scotton sees code switching as

having four functions: (1) code switching may be a series of unmarked code choices, with each switch unmarked choice because of shifting social or conversational context; (2) code switching may be the unmarked choice between bilingual peers; (3) code switching may be a marked choice showing noncompliance with some norm; and (4) code switching may be an exploration to find the unmarked code when it is not evident in a context (Myers-Scotton, 1993). The model treats the more frequently used code as the unmarked, matrix language and the less frequently used code as the marked embedded language. As Myers-Scotton notes, the matrix language-embedded language model is not just about linguistic code switching, but extends to any situation in which a speaker or writer manages different styles or registers. The papers in *Codes and Consequences* (1998), discussed below, apply the markedness model to style shifting more broadly.

Cultural Markedness

A main theme of markedness is the information content and information value of an element. Thus many researchers have seen markedness as an encoding of that which is unusual or informative. Conceptual familiarity with cultural norms provided by familiar categories creates a ground against which marked categories provide a figure, opening the way for markedness to be applied to cultural and social categorization. In the 1930s Jakobson had already suggested applying markedness to any opposition, explicitly mentioning such pairs as *life/death*, *liberty/bondage*, *sin/virtue*, and *holiday/working day*. Waugh (1982) extended this idea to note that oppositions like *male/female*, *white/black*, *sighted/blind*, *hearing/deaf*, *heterosexual/homosexual*, *right/left*, *fertility/barrenness*, *clothed/nude*, and *spoken language/written language* can all be treated as unmarked/marked cultural oppositions. And McCawley (1985) suggested that aspects of belief systems and even scientific theorizing could be analyzed as systems in which some assumptions are culturally unmarked. Interrogating our culture in this way prompts us to view our cultural architecture in terms of implicit assumptions. We refer to *poets* and *writers*, for example, establishing an opposition between the two (and implying perhaps that a poet is not a writer). And terms like *homeless* (as opposed to the logically possible but nonexistent word *homeful*) imply that having a home is the linguistically unmarked case.

The papers in Myers-Scotton (1998) demonstrate ways in which intentionality is conveyed by adopting systems of stylistically and culturally marked choices, as opposed to mere isolated examples. Such approaches hold promise as a descriptive technique for domains beyond language, and recent work has applied markedness to music, myth, and facial expression: among other things (see Hatten, 1994, 2004; Liszka, 1989). In his analysis of musical styles and television genres, for example, Hatten identifies marked and unmarked musical oppositions (such as minor vs. major modes) and demonstrates their correlation with theme (such as tragic vs. nontragic expression) and styles (Classical vs. Baroque). Following Hatten, Ron Rodman used markedness to model changing aesthetic norms in television police dramas, looking at the spread of jazz into the musical genres previously dominated by military themes. Markedness serves as the innovative aspect of style growth or style change. James Liszka has applied markedness to elementary forms of narration, specifically the folktale and the myth, shedding new light on Levi-Strauss's structuralism with a notion of transvaluation based on C.S. Peirce's concept of the interpretant: transvaluation is an interpretant which revaluates the markedness of a sign. Liszka and others have also investigated facial expression in terms of marked and unmarked oppositions (see Carpenter et al., 2011 for a recent study).

Against Markedness

As is evident, the more widely markedness has been used, the more difficult it is to treat as a coherent, unified notion. There has been an inevitable semantic drift as markedness has been applied to different grammatical domains (semantics, phonology, syntax), theoretical approaches (generative linguistics, functional linguistics), and extralinguistic concerns (code switching, cultural analysis). Does markedness remain a coherent notion? And can it be reduced to other concepts? Martin Haspelmath (2006), for example, distinguishes a dozen senses of markedness, which he groups into four larger classes: markedness as complexity, markedness as difficulty, markedness as abnormality, and markedness as a multidimensional correlation among various diagnostics. He argues that the term 'markedness' is superfluous, and can be replaced by less ambiguous concepts such as frequency asymmetries, phonetic difficulty, and pragmatic inferences.

I tend to prefer the view of markedness as a global semiotic principle, a means of exploring the parallels among the various markednesses. However, there is no denying that markedness has been extended and reshaped over the past century and reflects a range of loosely connected theoretical approaches for naturalness, language universals, defaults, and preferences in language acquisition and use. What connects various approaches is a concern for the evaluation of linguistic structure, though the details of how markedness is determined and what its implications and diagnostics are vary widely, as we have seen. (*See* Generative Grammar; Semiotics; Prototype Theory in Linguistics. For book-length discussions of markedness see Battistella, 1990, 1996; Andrews, 1990; de Lacy, 2006; Hume, to appear.)

Market and Nonmarket Allocation

Debra Satz, Stanford University, Stanford, CA, USA

Abstract

While markets are pervasive forms of social organization, there are many goods and services that we do not distribute through markets. For example, people buy, sell, and trade cars and shirts, but market exchanges of votes, babies, and legal justice are widely condemned. The market status of other goods – such as health care, human kidneys, and sex – is contested. What reasons can be given in favor of using and refraining from using markets? Many debates in the twentieth century have centered on this question. Typically, the debates over when and where a market is appropriate have focused on efficiency. This article will review the myriad reasons to use or refrain from using markets – including not only reasons of efficiency but also distributive justice and the effects of markets on democratic institutions and culture. This article also examines ways of enriching the list of distributive alternatives beyond the two poles of centralized plan and market such as gifts and lotteries.

While markets are pervasive forms of social organization, there are many goods and services that we do not distribute through markets. For example, people buy, sell, and trade cars and shirts, but market exchanges of votes, babies, and legal justice are widely condemned. The market status of other goods – such as health care, human kidneys, and sex – is contested. What reasons can be given in favor of using and refraining from using markets? Many debates in the twentieth century have centered on this question. Typically, the debates over when and where a market is appropriate have focused on efficiency. This article will review the myriad reasons to use or refrain from using markets – including not only reasons of efficiency but also distributive justice and the effects of markets on democratic institutions and culture. This article also examines ways of enriching the list of distributive alternatives beyond the two poles of centralized plan and market such as gifts and lotteries.

What Is a Market?

Modern economic textbooks rarely offer a definition of what precisely constitutes a market. The Shorter Oxford English Dictionary defines a market as "a meeting or gathering place for the purchase and sale of provisions or livestock" or as the "action or business of buying and selling." However, markets are not merely places, nor are they best understood in terms of episodic individual transactions. Functioning markets actually require many conditions that need to be in place. For example, there must be enough exchanges so that people can use price signals to coordinate their behavior, there must be background property rules, there must be mechanisms for information to flow, and there must be the curtailment of monopolies (McMillan, 2002). Many of the conditions that working markets require are dependent on state action. For this reason, it is a mistake to see market and state as simple contrasts.

Markets are mechanisms used for the production, circulation, and valuation of many goods and services. Their desirability rests on three of their noteworthy features: they are efficient, impersonal, and oriented to individual preference and choice. Let us consider these features in more detail.

Since rational individuals will only exchange goods and services when they have something to gain, markets will be efficient – purging the economy of the less desirable goods and moving the trading parties to preferred positions. Economists refer to this property of markets in terms of 'Pareto optimality.' A state of affairs is Pareto optimal when no one can be made better off (i.e., their utility increased) without someone else being made worse off (i.e., their utility decreased). An important result in economics, the so-called 'fundamental theorem of welfare economics,' shows that in a world in which everyone could trade everything – including futures, uncertainty, and so on – the allocation of resources would be Pareto optimal. This theorem formalizes the earlier conjectures of Adam Smith and others, that participation in competitive markets would lead rational self-interested individuals to produce, as an unintended consequence of their private actions, collectively good results.

Markets are also impersonal, suitable to regulating the interactions of strangers. They abstract away from particular features of a participant, such as his race, religion, or sexual orientation and focus only on his assets – what is being offered to buy or sell. The impersonality of market relations means that each individual is indifferent to his trading partners at any time. He has no precontractual obligations to those he trades with and is free to consider only his own interests in pursuing an exchange.

In market exchange, the parties also express their own individual preferences, pursuing their own sense of what is good, independent of what the state or others value. Markets are thereby conducive to individual freedom: they accommodate individual preferences without passing judgment upon them. By decentralizing decision making, markets give individuals a significant measure of freedom over their circumstances. Furthermore, one is free to walk away from any exchange – the same deal can be struck elsewhere, as it were. Albert Hirschman (1970) has termed this latter feature the power of 'exit,' to distinguish it from the power of 'voice' (i.e., speaking up).

A Contrast

The modern, neoclassical conception of economics, developed in the late nineteenth and early twentieth centuries by

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63048-9

Edgeworth, Robbins, and Jevons, treats the market as something obvious and simple. In the standard neoclassical general equilibrium model of a market economy formulated by Leon Walras (1926/1954), commodities are identical, the market is concentrated at a single point in space, individuals have complete information about the exchange commodity, and exchange is instantaneous. There are, accordingly, no costs in enforcing agreements and no important distinctions among kinds of markets.

The neoclassical treatment of markets has produced important mathematical results such as the fundamental theorem, and also allowed for the development of powerful models that can characterize the equilibrium properties of an entire economy. However, it depends on viewing markets as economic mechanisms whose operation can be understood in abstraction from the particular kinds of goods being exchanged and the relationships between the participants. In the neoclassical conception of markets, it does not matter whether what is being traded is oranges, sexual services, or credit – the nature of market exchange is seen as the same in each case. The participants are considered interchangeable, and, given the opportunities each has for exit, it is assumed that no party can exercise significant power over another. In Paul Samuelson's words, "in a perfectly competitive market, it does not matter who hires whom: so let labor hire 'capital'" (Samuelson, 1957, p. 894). The result is that the market is viewed as a private realm, whose smooth operation leaves no room for political intervention: intervention is justified only when markets in some goods fail to be established or are inefficient.

By contrast, the classical economists – among them Adam Smith, David Ricardo, and Karl Marx – offered distinct theories of the operation of markets in different domains and focused on the opposing interests of the three main social classes – landlords, capitalists, and workers – who came together to trade and between whom the produced social wealth was to be distributed. Not only were markets viewed as political, in the sense that they depended on legal property rights, but it was also recognized that their functioning in certain realms inevitably raised questions relevant to the structure of public life. For example, the classical economists noted that the market between buyers and sellers of goods such as oranges differs importantly from the market between buyers and sellers of human labor power. This is because the latter kind of market involves a good that has the highly unusual status of being embodied in a human being. While we do not have to worry about the noneconomic effects of a market on fruits, we do need to worry about whether a particular market in human labor power produces passivity, alienation, greed, or indifference to others.

The classical economists saw the marketplace as a political and cultural as well as an economic institution, where differing interests wielded power and where some types of exchanges had constitutive effects on their participants. Adam Smith (1776/1937) worried not only about the tendency of the owners of capital to collude and thus block market competition but also about the effects of a fragmented and monotonous division of labor on the ability of workers to participate in political life.

Criteria for Assessing the Use of Markets

The most famous modern debates about the legitimacy of market allocation versus its alternatives have focused on its efficiency. Consider, for example, the debate between socialist economist Oskar Lange and conservative economist Friedrich Hayek, which took place during the 1930s, when the Soviet experiment was underway. Lange and Hayek debated whether a noncapitalist economy with few market structures could experience economic growth. Lange argued that an ideal planned economy could allocate resources in a more optimal manner than a perfectly competitive market economy. In rebuttal, Hayek pointed out that planned economies have a tendency toward bureaucratic sclerosis, a lack of accountability and high information processing costs.

Each side raised important considerations. Each side had a point. However, from many perspectives their debate about markets can be criticized as narrow and conceptually impoverished. The debate not only tended to operate as if there were just two choices – command and control centralized planning and the system of unregulated markets – but also posed the issue about market or nonmarket choice solely in terms of efficiency.

If we see the market as a complex heterogeneous institution, which brings people into different kinds of relations with each other for different exchanges, then we can also see why the use of markets can raise other concerns besides efficiency. From this broader perspective, not only efficiency but also considerations of fairness as well as the effects of the market on the political structure of power and on human well-being are relevant to determining when and where markets should allocate goods and services and where other institutions should be used.

Efficiency

Through the use of prices, markets indicate what millions of goods and services are worth to sellers and buyers. They thereby function to apportion resources efficiently: they signal to sellers what to produce, to consumers what to buy, and to capitalists where to invest their wealth. The continual adjustments of supply and demand, registered in changing prices, allow markets to 'clear' inventory. When inventory is cleared, there is no excess demand or supply: supply equals demand at some price. The efficiency benefits that markets produce constitutes an important prima facie case for their inclusion in an economy. Furthermore, at least to date, we know of no mechanism for inducing innovation on an economy-wide basis that is as successful as market competition.

In certain circumstances, however, markets can fail to be efficient. While in the model of an ideal market, the transaction costs involved in exchanges are taken to be zero, and each participant is assumed to have perfect information and acts solely on the basis of his or her rational self-interest, it is well recognized that these assumptions do not always hold in reality. Thus, the standard theorems connecting markets and efficiency are usually coupled with the identification of 'market failures,' circumstances in which the efficiency effects of markets are either inoperable or eroded. For example, markets fail when and where certain effects of an exchange – which economists call 'externalities' – are not fully absorbed by the exchanging parties

and are passed on to third parties. In some circumstances, these external costs constitute public bads: the defacement of the landscape, pollution, and urban decay are notable examples. Markets also fail where there are natural monopolies, or technologies that give rise to economies of scale, thus making only monopolistic or oligopolistic firms viable.

In the last several decades, work within mainstream economics has shown that market failure may be more widespread than previously supposed. This work emphasizes the ubiquity of imperfect and asymmetric information held by the exchanging parties (Akerlof, 1970) as well as the fact that in many exchanges the parties cannot easily control one another's behavior. (Consider the costs of supervision that employers pay to make sure that their workers are actually working.) Economic models now take into account the incentives agents have to manipulate information and outcomes in order to press their own advantages. Thus, agents may act as if they were willing to pay less for goods and services than they really are, or threaten to withdraw from a trade entirely. It is now recognized that people can act in ways that prevent markets from clearing even in competitive equilibrium – there will be persistent excess supply or excess demand. This is because if one party wants to have power over the other, it can achieve this by giving the other something to lose, so that it now costs something to 'exit.' Thus, because not all prospective borrowers can find loans and not all those who seek jobs can find them, those who do have a strong interest in complying with, respectively, the banks or owners (Stiglitz and Weiss, 1981). The power that banks thus acquire over their creditors and owners acquire over their workers gives these markets a political character. One might say that this recent work emphasizing strategic action, incomplete information, and transaction costs gives mathematical precision to some of the earlier insights of the classical economists (Bowles and Gintis, 1993).

In an important sense, externalities are everywhere. Almost any exchange in an interdependent society is likely to impose a cost on third parties. High-rise apartment towers block the sun of neighboring houses, cars bring congestion, and noise circulates. We need some guidance, then, as to which externalities are serious enough to merit intervention in a market. This is a question for ethics and politics, not economics.

Various solutions to market failure have been proposed including state intervention in the marketplace, expansion in the number of markets (e.g., allowing externalities themselves to be priced by the market), and the use of nonmarket alternatives such as bargaining and negotiation. The point of such solutions is to restore efficiency.

In thinking about the ways that markets contribute to efficiency, we should note that the actual efficiency outcomes of the market depend on the initial distribution of endowments and assets. This initial distribution is not itself part of the definition of Pareto optimality. A state of the world can be Pareto optimal, even if its original distribution was based on theft and fraud or was otherwise unfair. In order to justify market outcomes, or to use Pareto optimality normatively, the theory of market efficiency needs to be supplemented with a theory of distributive justice. Some theories of distributive justice focus on the legitimacy of the initial distribution of assets while others focus on the legitimacy of the distributive inequalities that the market produces.

A related point is that efficiency interpreted as Pareto optimality has only modest moral content. This is true for several reasons. First, Pareto optimality deals exclusively with efficiency and pays no attention to distribution. A Pareto optimal state can thus be a state of social misery for some. Simply consider the case in which the utility of the downtrodden cannot be raised without lowering the utility of the millionaires. Second, the Pareto criteria dispenses with interpersonal comparisons, so that we cannot compare the contribution a meal makes to the poor man's utility with that it makes to a millionaire's (Sen, 1987).

These considerations bring home the point that efficiency is not the only value we have reason to care about. Even if certain markets are efficient, we may sometimes have good reason to block them or to further regulate them. The fact that a market in political votes might be efficient does not suffice to justify such a market.

Freedom

Market allocation is often defended in terms of freedom. Proponents cite a range of important effects that markets have on an individual's ability to develop and exercise the capacity for liberal freedom. Each of these effects, they argue, depends on leaving the market domain largely cordoned off from political interference. Markets (1) present agents with the opportunity to choose between a large array of alternatives, (2) provide incentives for agents to anticipate the results of their choices and thus foster instrumental rationality, (3) decentralize decision making, giving to agents alone the power to buy and sell things and services without requiring them to ask anyone else's permission or take anyone else's values into account, (4) place limits on the viability of coercive social relationships by providing (relatively) unimpeded avenues for exit, (5) decentralize information, (6) (may) enhance individuals' sense of responsibility for their choices and preferences, (7) allow people to practice and try out various alternatives, (8) create the material wealth that is a precondition for the possibility of having decent alternatives, and (9) allow liberal individuals to cooperate without having to agree on a large range of questions of value (Friedman, 1962; Nozick, 1974).

Liberal theories that assign substantial weight to individual freedom thus allot a central role for market allocation, pointing to the market realm as a place where the capacity for individual choice – indeed, where the liberal individual – is developed. As liberal theorists are likely to emphasize, respect for markets in goods and services can be an important way of respecting individual (and divergent) conceptions of value. In a market system, there is no preordained pattern of value to which individuals must conform and exchange gives to individuals the freedom to pursue distinct aims. In fact, the market leaves people free not to choose to sell or buy a particular good on the market.

The liberal theory of freedom is essentially (although not entirely) a negative one, emphasizing the space markets provide to individuals to pursue their private ends free from external intrusions by the state or other people. This liberal theory linking freedom and markets has been criticized for not attending to the preconditions for its own realization. These

preconditions include the existence of some realms that are protected from the market (Polanyi, 1971). For example, most liberals recognize that it is incompatible with liberal freedom to allow a person to sell herself into slavery; free people require rights to consultation, self-judgment, and control over the conditions in which they act. The formation of a market agent also requires education: there is no 'infans economicus' who is born with the developed ability to choose in a market. Some theorists have further argued that the securing of liberal freedoms requires the guaranteed provision of a minimal level of basic goods such as health care, food, and housing and may therefore require the regulation or blocking of certain markets (Satz, 2010).

Human Flourishing

Market allocation has often been defended on the grounds that markets, by satisfying people's preferences, contribute directly to human happiness and flourishing. In addition, by stimulating economic growth, markets have the potential to eradicate the poverty and hardship that is everywhere the enemy of a decent quality of life. Certainly, the market makes important contributions to the satisfaction of human wants. However, in considering the effectiveness of the market in maximizing overall human well-being, several considerations need to be taken into account. First, satisfaction of the subjective preferences of an individual agent may not provide that agent with well-being. A lot depends on the content and nature of his or her preferences. Agents may have preferences for things that do not contribute to their overall good, preferences that are mere accommodations to their circumstances, preferences they themselves wish they did not have, preferences based on false information, and preferences that are instilled in them by the market. In some such examples, the case for regulation can be made on paternalistic grounds, excluding exchanges born of desperation (such as selling oneself into slavery), lack of information, and imprudence (Sunstein, 1991).

Second, the market recognizes only those preferences that can be backed up by an ability to pay. The poor man's preferences for a good meal are invisible. Indeed, the notion of 'preference' itself does not distinguish between kinds of preferences, only degrees of strength. Thus, the market cannot distinguish between urgent human needs (the poor man's desire for nourishment) and mere whims (the rich man's desire for a fine burgundy), but urgent needs are more important to meet than mere wants (Scanlon, 1975). Third, there are important sources of satisfaction that do not go through the market: public goods that, by their nature, do not go through the market and interpersonal relations that may be spoiled if they become part of the market's transactional network. So care must be taken to avoid ignoring those preferences that are not expressed on the market.

Fourth, empirical studies point out that the contribution of material wealth to a person's well-being tapers off above a certain level of income. Money correlates with happiness, but the correlation diminishes with additional income.

Some critics have claimed that markets promote an inferior form of human flourishing. This criticism has a wide interpretation and a narrow interpretation. On the wide interpretation, markets everywhere shape and socialize people in the wrong way. They are taken to do this by promoting selfish behavior, making people more materialistic, and dulling people to important distinctions of value to which they should be responsive.

This worry about markets is sometimes posed in terms of the metaphor of infection – that market norms and relations will spill over and contaminate nonmarket realms such as friendship and love. Thus, it has been alleged that markets erode our appreciation of the true value of other people, since they lead us to think of goods and people as exchangeable items. This wide interpretation of the market's negative effects on human flourishing has only weak social scientific support. There is little evidence that people are greedier in market societies than they were in peasant economies, that they devalue love and friendship, or that they are now less likely to engage in moral behavior than in the past (Lane, 1991).

A narrower interpretation of this humanistic criticism is that some (but not all) markets have bad feedback effects on particular human behaviors. Studies have shown, for example, that economics and business students (who presumably are more likely to govern their behavior by the axioms of neoclassical economics than are literature or sociology students) are uniquely uncooperative in solving collective action problems (Marwell and Ames, 1981). Other studies have pointed to similar 'crowding out effects' – cases in which the appeal to a market incentive crowds out the other reasons a person has for performing the action. Bruno Frey and his colleagues found that people were less willing to host a noxious waste facility after monetary compensation was offered than they were without the money. In some cases, when individuals are civically minded, using price incentives will backfire and not increase supply. Crowding out therefore has implications for efficiency as well as for human character and flourishing (Frey and Oberholzer-Gee, 1997).

Richard Titmuss (1971) had earlier claimed that allowing blood to be sold and bought as a commodity would drive out altruistic blood donation by turning the 'gift of life' into the monetary equivalent of 50 dollars. People would become less willing to give blood freely as market distribution became more prevalent, for their gift loses its benevolent meaning. (Blood quality would also be lower since altruistic donors have no incentive to lie about the quality of their blood, while commercial donors clearly do.)

Titmuss aimed to show that markets have broader incentive effects than economists had previously supposed. His account also shows that markets can undermine flourishing if they lead us to fail to act from reasons we would prefer. If this is so, then sometimes market regulation – including prohibition of certain exchanges – may even shore up liberal freedom by allowing us to get the choice that we most want. (Consider the role of minimum wage laws and prohibitions on vote selling from shrinking people's opportunity sets over time.)

The market's negative feedback on motivation was the concern of diverse thinkers such as Adam Smith, Karl Marx (1977), and John Stuart Mill (1970), who each worried that labor markets that rendered workers as mere appendages to machines would cripple their capacity for independence and political participation. Each thinker noticed that labor market exchanges had a constitutive effect on the parties to the exchange: workers who engaged in servile, menial, and degrading work were likely to be servile citizens.

Where markets have significant feedback effects on human motivation, there is an additional possible case for social regulation. It is circular to justify markets on the grounds that they maximally satisfy individual preferences in cases where those preferences are themselves shaped by the market. At the very least, recognition of the endogenous nature of some preferences leaves the question of institutional design open since there may be other mechanisms that generate and satisfy more preferences.

The Nature of the Goods Exchanged

Liberals have traditionally argued that many of the problems that unregulated markets raise with respect to the values of efficiency, justice, freedom, and well-being can be attenuated through state intervention. We can redistribute income and regulate consumption through taxation, publicly provide for social goods such as schools and roads, and establish a minimum level of health care for all citizens. Other social institutions that, in turn, encourage values such as honesty, reciprocity, and trust can be called upon to support markets.

There is a different criticism of the market that cannot be addressed through market regulation but requires that the use of the market be blocked. This criticism focuses not on the negative consequences of market exchanges but instead on the ways that markets undermine the intrinsic nature of certain goods. The theorists who make this criticism reject the use of markets in certain domains and for certain goods categorically.

Markets are often taken to be neutral means of exchange. By this proponents mean that the market does not distinguish between my ethical valuation of a good and yours. I may value my Bible infinitely while you assign it a dollar price, but the market is compatible with both of our understandings of this good. The market responds only to effective demand, not to the reasons people have for wanting things. When the market puts a price on a thing, it leaves the ways that people value it untouched.

In reality, this view of market neutrality is overstated. Some goods are changed or destroyed by being put up for sale. The most obvious examples of this phenomenon are love or friendship. A person who thought that they could buy my friendship would simply not know what it means to be a friend. A proposal to buy love, prizes, honors, friends, or divine grace is conceptually incoherent: it is the nature of these things that they cannot be bought.

Various arguments have been given to show that many goods are not properly conceived of as market commodities. Some of these arguments depend on the idea that certain goods are degraded and corrupted when sold, or that some sales are inherently alienating to, or exploitative of, the seller (Anderson, 1993; Sandel, 2012; Walzer, 1983). Candidate goods include sex, reproductive labor, adoption, military service, health care, prisons, and political goods such as votes and influence.

Consider sex and reproductive labor. Some feminists have argued that markets are inappropriate for exchanging goods that place people in personal relations with each other. They argue that when sexual relations are governed by the market, such as in prostitution, not only is an inferior good produced since commercial sex is not the same as sex given out of love but also the dignity and freedom of the prostitute is compromised. Because practices such as prostitution are alleged to allow women's bodies to be controlled by others, these arguments conclude that women's freedom and dignity requires that their sexual and reproductive capacities remain market-inalienable (Radin, 1996).

Given the relatively poor economic opportunities open to many women, one may doubt whether paid pregnancy or prostitution is comparatively worse for women's freedom than the alternatives. For example, is prostitution more constraining than extremely low-paid, monotonous assembly-line work? Does commercial surrogacy really place more extensive control over a woman's body than other acceptable labor contracts such as those given to professional athletes? To answer these questions may be more a matter of looking at the empirical consequences of markets in sex and reproduction, and the history of women's roles in the economy and the family, than of examining the intrinsic nature of these goods. The charge that prostitution undermines dignity is different. We cannot ascertain whether a person's dignity is compromised simply by looking at her options.

Of course, even if the corruption argument is true with respect to a certain good, that does not by itself tell us whether or not we want to block markets in that good. In a liberal society we give people the right to make inferior choices, provided that they do not do harm to others.

Democracy

A special case is often made for regulating or banning markets so as to ensure that democratic institutions are supported. This case has several components: (1) a theory of those political goods that must be provided to everyone equally in a democracy – goods such as votes, political rights, and liberties; (2) a theory of the economic preconditions of democracy; and (3) a theory of the kind of institutions that foster the development of people likely to support democratic institutions and function effectively in a democratic environment. It is easy to see that democracy is incompatible with property qualifications on the right to vote, slavery, and vote selling. Current debates center on whether democracy requires greater regulation of the political process including public funding of elections and campaigns, whether democracy requires greater regulation of the economy to allow for 'voice,' and whether expanding the market in education would enhance or inhibit the development of democratic citizens.

Regulation vs. Alternatives

Arguments that purport to show that markets in some good do not promote freedom, happiness, well-being, or some other value do not directly enable us to conclude that such exchanges should be blocked. Even if markets interfered with or failed to promote certain values, interference with them might be worse overall from the point of view of those same values. Suppose, for example, that the only feasible institutional alternatives to markets all involved significant amounts of coercion, or suppose that a legal ban on a market simply drove the exchanges underground in a thriving black market in which the participants suffered additional harms (Satz, 2010). An

example of this effect can be seen in the case of the legal ban on addictive drugs such as heroin and cocaine. Conservatives frequently cite the costs of 'overregulated' markets such as rent control and limits on parental choice with respect to education. Therefore, a full assessment of market allocation must take into account the alternatives and the likely consequences of different interventions.

Other Forms of Market Regulation

Most egalitarians endorse the use of markets combined with redistributive taxation to redress the inequalities that market processes often produce (Dworkin, 2000). In this way the market's efficiency is allowed to function, and then transfers occur after the fact. (Of course, taxation itself has effects on the market's efficiency, as rational agents will change their behavior to avoid or diminish their own payments.) The important egalitarian goal is to ensure that the operation of markets do not undermine society's commitment to treat all of its citizens fairly.

Other forms of market regulation besides ex post tax and transfer mechanisms have been suggested. These include ex-ante restrictions on the transferability of income and wealth, as in ownership requirements that stipulate that owners must be active participants in the community in which their property is located, and restrictions as to what people can do to the things they can sell, as in historical building codes.

Nonmarket Allocation

There are important alternative mechanisms for distribution that do not rely on a market. In the twentieth century, the most important alternative allocation mechanism has been government provision. Government decision has allocated such goods to individuals as citizenship; social security; infrastructure such as roads, highways, and bridges; and education up to early adulthood.

Many allocative decisions are shaped neither by the government nor by the market. These include distribution through gift, lottery, merit, the intrafamily regulation of work and income, and other principles such as seniority and need. Consider a few cases.

In the United States, the lottery has been used to allocate resources literally bearing on issues of life and death. Military service, especially during wartime, has often been selected for by lottery; the alternative has been to allow people to volunteer. Lotteries have also been used to distribute licenses for low-power television and radio stations by the Federal Communications Commission, determine access to immigration, and distribute admission to magnet and charter schools.

College admission, election to professional associations, and the award of prizes have been governed neither by market norms nor by state decree but by selective principles of merit and desert. Need has been central in allocating organs for transplantation.

In each of these cases, one can compare the allocation achieved with that which would likely have been achieved through a market, in terms of the broad list of criteria specified above.

Market Geographies

Abstract

A commonly accepted definition of the concept of *market area* is that of the territory (or section of the geographic space) over which the entirety or majority of sales of a given good or service supplier takes place. It is the territorial expression of the supplier's clientele. The market area is much more than an ex post map depiction of a purely aspatial microeconomic process that defines customer–supplier relationships. In his 1870s work, the German economist Launhardt is credited for unveiling the novel idea that suppliers' success to sell their output in a market economy is shaped by considerations of transportation cost and position of competing suppliers one relative to another in a geographic space. The theory of market areas that grows out of his work emphasizes demand-oriented processes in shaping the spatial organization of economic systems and population settlements. Launhardt's pioneering ideas gave life to several research traditions in the social sciences. One emphasizes microeconomic processes and it is manifested in the seminal work of Christaller, Lösch, Greenhut, and others. A second research orientation is dedicated to the geometric characterization of market areas under alternative spatial behavioral and structural contexts. Third, the prescriptive approach looks at market areas as they ought to be delineated according to some system optimization criteria. Finally, revolving around the implied delineation of market areas through the social physics principle of spatial interaction, the fourth tradition has become a pillar of modern business geographics and spatial business intelligence. This article traces the roots of the concept of market area, the development of the four traditions outlined above, and discusses the relevance of the concept to modern social and behavioral sciences.

Market Area as Territorial Expression

A market is the set of actual or potential customers of a given good or service supplier. These consumers may be segmented according to any of a number of sociodemographic dimensions, including their age, gender, lifestyle, as well as their location relative to the supplier's own geographic position, to the position of other suppliers, and to the position of other consumers. The territory (or section of the geographic space) over which the entirety or majority of sales of a given good or service supplier takes place constitutes this supplier's market area. The same concept is also known as 'trade area,' 'service area,' 'hinterland,' or 'catchment area' across various fields of social and behavioral sciences.

In modern market-oriented economic systems, in which production and consumption are uncoupled, consumption (demand) is rather ubiquitous in geographic space (at home, at work, on the road, etc.), while production and distribution functions (supply) are limited to a few locales. The incongruity in the spatial organization of demand and supply is mediated by the mobility of economic agents or the availability of delivery services: market places emerge when consumers are mobile; home delivery requires suppliers to reach out to their customers; and the age-old institution of periodic markets emerges in sociocultural environments where production and consumption agents are mobile. In all cases, the concept of market area serves to capture the notion of territorial expression of a supplier's clientele. It applies to retailers and service marketers as disparate as grocers and other retailers (Applebaum, 1966; Allaway et al., 1994), health care providers (Fortney et al., 1999; Frech et al., 2004), and library branches (Jue et al., 1999; Donnelly, 2014). Sometimes, access to the service is highly regulated, as in the case of some public services where jurisdictional considerations predetermine the shape and geographic extent of market areas (school districts, for instance) (Yeates, 1963; Dost, 1968).

Goods and service providers are known to seek common locations in geographic space so as to share externalities created locally by agglomeration or clustering. Towns throughout the world, many cities, spontaneous urban retail and business districts, even planned shopping centers, owe their existence to such agglomerative forces. Because it is commonplace for many or all businesses belonging to these geographic clusters to share the same consumer bases, the narrow definition of market area given in the previous paragraph can be extended from single providers of goods and service providers to spatial clusters of them.

Why firms locate where they do is the central question of location theory. An early school of thought pioneered by von Thünen approached this question as a least-cost problem. On the other hand, the market-area analysis school emphasizes demand-side considerations by framing the locational decision(s) of the firm as a search for site(s) that command the largest number of customers. It is a straightforward consequence that, for a given spatial distribution of identical consumers, the size and shape of a firm's market area are indicative of the success of the firm at that site. However, the same does not hold once it is recognized that all households within a market area do not have the same disposable income. In fact, market geographies are then better encapsulated as a reflection of income geographies than of sheer population counts. The market-area analysis school provides the economic underpinnings for a substantial theoretical body of knowledge on the processes of spatial organization of businesses in consumer-oriented industries (Greenhut, 1956), and of market places, retail districts, and of settlement centers into hierarchical systems (Christaller, 1933; Berry and Parr, 1988). The market-area approach continues to provide the tenets for applied research in retail location analysis (Ghosh and McLafferty, 1987), public facility planning (Thisse and Zoller, 1983; Church and Murray, 2009), and spatial and territorial planning (Von Böventer, 1965). Interestingly, it remains

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72031-9

a fundamental frame of reference in an era where much information on marketed products and services is obtained through electronic means (including social media), and where much of the trade is carried out electronically (e-commerce).

Economic Underpinnings

It was remarked above that a firm's market area is the territorial expression of the firm's clientele. However, the market area is far more than an ex post map depiction of a purely aspatial microeconomic process that defines customer–supplier relationships. In his 1880s work, the German economist Launhardt (1882) is credited for unveiling the novel idea that a firm's success in selling its output in a market economy is shaped by considerations of transportation cost and of position of competing firms, one relative to another in the geographic space. In fact, it has only recently been established that the very same ideas were in fact articulated four decades earlier by the German economist Rau (1968) in a little known letter to his colleague Quintelet.

Let us consider initially the simplified possible case, that of a single firm supplying a single good to a population of identical consumers scattered over a certain geographic territory. If all consumers are assumed to have an identical demand curve that is elastic to the good's 'real price' (defined as the sale price plus transportation cost), individual demand drops with distance from the firm location. The monopolistic firm's market area extends outward to the circular perimeter where demand falls to zero. This distance is known as the range of the good. The market beyond this point remains unserved by the firm, a situation that may raise serious social equity concerns if basic needs of the population remain unmet as a result. For the sake of increasing its sales and reducing its unit production cost, the firm may decide to serve consumers outside the normal market area. It may accomplish this in several ways. One approach involves absorbing part of the real price applied to more distant consumers. Any spatial pricing system aimed at accomplishing this goal subsidizes remote consumers and discriminates against nearby buyers. Similar economic circumstances are commonplace when several firms at different locations compete for consumers. Since firms have more control over their nearby customers, they may seek to discriminate against them, whereas consumers at the margin of market areas may enjoy lower prices ensuing interfirm price competition.

When a second firm whose geographic position is different from that of the first one supplies the same good, the situation becomes more complex. Each firm commands sales in the same circular market area if they are located far enough from each other (i.e., over twice the range of the good). The two firms enjoy monopolistic profits that may entice new firms to start business. New competitors can be expected to locate in the interstitial space between monopolistic market areas so as to command the largest possible volume of business and avoid competition. This leads us to the alternative condition where firms find themselves close enough to each other to create competition at the edge of their respective monopolistic market areas. The introduction of a competitor establishes another type of boundary line where real prices are equal. The economic significance of this boundary is considerable because it delineates the market areas of competing firms, and consequently determines their sales and profits. Remarkably, as indicated by Isard (1956), this boundary is optimal and socially efficient. Working with Launhardt's (1882) assumption that firms do not charge the same sale price, the boundary line is a hyperbolic curve defined by the equation of the difference of sale prices to the difference of transportation costs to firm locations. The American economist Fetter, who independently discovered the same economic principle, coined the phrase 'economic law of market areas' in 1924.

Figure 1 illustrates the law of market areas under two different conditions. When firm B charges a sale price higher than that of firm A, firm A has a cost advantage over B that translates into a larger market area. The market boundary is hyperbolic and closer to B than to A. In the special case where firms charge identical sale prices, neither competitor has a special advantage. The two market areas are equal and are separated by a boundary line that is a degenerated hyperbola equidistant from the two firm locations.

As indicated above, free entry of firms affects the size and shape of market areas. Christaller (1933) and Lösch (1954) argued that free entry of new firms would compress the circular market areas defined by the range into hexagons forming a lattice covering the entire territory and that firms position themselves at even distances from each other. Geometrically speaking, these hexagonal market areas are proximal areas, also known as Thiessen polygons (or Voronoi diagrams), drawn by intersecting the perpendicular bisectors of lines connecting adjacent firm locations (Okabe et al., 2000). These geometric constructs are fundamental elements of geographic information science. When firm locations are not perfectly equidistant, Thiessen polygons are distorted, but their economic interpretation is unaffected. This happens to be a very general case in practice due to departures from simplifying theoretical assumptions, such as when population (and therefore demand) is not evenly distributed across the geographic space.

Figure 1 This diagram represents the market areas of two firms, A and B. When A and B charge equal sale price, market areas are separated by the vertical straight line. The hyperbolic curve separates market areas when B charges a price higher than A.

The theory of spatial organization advanced by Christaller and Lösch was also extended to encompass multiple goods – from the most to the least ubiquitous – to which corresponded multiple overlapping layers of hexagonal market areas. One area of deficiency of this theory was to underrate mutual interdependencies between markets for different goods and their territorial expression, the market areas. Demand-side linkages between markets are particularly meaningful to market-driven industries. One such linkage is created by consumers' effort to reduce the transactional cost of shopping by means of combining the purchase of several goods on the same shopping trip. Multipurpose shopping, as this practice is called, reduces the geographic dispersion of firms where these goods are purchased. Because of enlarged market areas, sites where a larger range of goods is marketed are consequently placed at an advantage over others.

Spatial Analysis

The previous section introduced the possibility of polygonal, hyperbolic, and circular market areas. The question arises now what shapes are possible and what conditions bring them about. Since market areas constitute a model of the geography of demand, knowledge of geometric and topologic properties of market areas (Hanjoul et al., 1988) may shed some light on various issues of interest to urban and regional scholars such as the life cycle of business districts, people's modality of usage of the urban space, or the quality of geographic accessibility to amenities (social services, health, and cultural facilities, for instance).

It turns out that market areas may take any of a large number of different shapes depending on how the perceived cost of traveling over space is related to the physical distance. For instance, the hyperbolic areas mentioned earlier are related to a linear transportation cost function. When transportation cost increases as the square root of distance (i.e., the cost of the extra mile traveled drops as the trip gets longer), market areas are elliptic. Circles arise when transportation costs follow the log-transform of distance. In contrast to hyperbolae, circular and elliptic market areas reveal that the firm charging the higher sale price manages to serve consumers in the direction opposite to its main competitor only if they are located rather close. In these conditions, distant consumers in fact have an economic advantage in bypassing the nearby firm to patronize a more distant but cheaper firm. This economic behavior stands in direct contradiction with common intuition on the matter, yet it can be proved to result from the decreasing marginal cost of transportation. The same fails to hold for a transportation cost that is linear in distance or increases more than proportionately with distance (the latter condition being very unlikely in practice). It follows that firms cannot automatically treat consumers that are distant from competitors as a 'safe' market. Determining how secure a geographic segment of the market is depends not only on where the segment lies with respect to firms but also on the structure of transportation costs.

Another interesting property of geographic markets is the inclusion of a firm location in its own market area, that is, whether a firm serves in the direct vicinity of its physical location. Intuition suggests that a firm, whatever the economic and geographic environment it is operating in, ought to be able to competitively serve consumers at its door steps. Mathematical arguments can be used to show that this expectation is sound in most prevailing conditions, namely, when transportation costs conform to a concave function of physical distance. In the unlikely event of transportation cost rising at an increasing rate, however, the firm charging a higher sale price would fail to serve nearby consumers if it is close enough to its main competitor. Quite understandably, this situation translates into greater vulnerability to competitive pressures of the market place.

Prescriptive Market Areas

As pointed out earlier, the distribution function of a market economy fulfills the essential role of bringing the demand to clear with supply. As demand and supply are grounded in specific locations, and as the clearing process involves expenses on shipping between locations, the allocation between supply and demand points in space is a pressing consideration of most cost-conscious organizations. This process can be achieved with efficient use of resources according to what has been termed the 'transportation problem.' The spatial pattern of allocation from supply points to demand points derived from the transportation problem is prescriptive in that it conforms to an overarching objective of optimization of shipping costs across the system. It may not reflect the patterns that would emerge spontaneously if individual economic and social agents were to decide on this matter, a view point that is more consistent with the perspective presented in the next section of this article.

Various sorts of organizations resort to delineating service areas on the basis of the prescriptive flows between localized agents in the spatial system. This includes corporate entities serving a specific customer base through a network of facilities, like warehouses. These warehouse networks are constantly assessed by their corporate parent in terms of their capacity, number, and service area configuration so as to maintain system-wide efficiency. Public agencies in charge of siting facilities (e.g., libraries, schools, police stations) also follow similar approaches. In many cases, market areas exhibit a strong tendency to be compact and contiguous regions as they are born from the principle of geographic accessibility maximization. It is, however, not a required property that they be compact or contiguous. In fact, entire classes of problems are notorious for their departure from the ideal of compact market areas. Capacitated facility planning problems differ from others because capacity constraints are imposed on the ability of facilities to accommodate demand. When the constraint is closely binding, nearby customers may be assigned to a more remote facility in the interest of satisfying the constraint, but a trade-off occurs as a more distant group of customers may find themselves assigned to this facility because it is small enough to not exceed the capacity constraint. A broader class of so-called location-allocation models subsumes problems that take the location of facilities as given and seek only to distribute flows between supply and demand points.

Behavioral Viewpoint

The perspective outlined in Section Economic Underpinnings may be crucial to foster our conceptual understanding of market areas, but too often it fails the test of operational dependability for the simple reason that it assumes that a locale falls entirely into one or another market area. Business practitioners and applied social scientists have argued that a firm's ability to command consumers does not stop at the boundary of its market area, but rather that that ability extends past that boundary and into the areas imputed to other firms. The argument continues as follows. Because of a host of other factors explaining people's selection of a firm and because of interpersonal variations in preferences, demand is best viewed as the outcome of a probabilistic process. As a result, markets are contestable to a degree that is determined by the degree of interpenetration of firms' respective drawing power on consumers. Firms that are seen to be close substitutes by a certain segment of consumers (consumers with a similar socioeconomic profile and/or living in the same neighborhood) would also be engaged in fierce competition for this segment and their market shares would be pretty much on par. Conversely, when cross-elasticities between firms are low (limited substitution), the local market is rather captive.

The dominant paradigm to frame a more behaviorally grounded view of spatial competition and the structuring of market areas is that of spatial interaction, according to which one's attraction to a firm (i.e., likelihood to buy from this firm) is directly related to the attractiveness of this firm and inversely related to the travel cost to it.

In this view, a firm's market area is recast as the territory where attraction to this firm is greater than to any other firm. Since the 1930s, the approach has been known as Reilly's law of retail gravitation (Reilly, 1929; Huff, 1962) by analogy with Isaac Newton's law of planetary gravitation. Of course, the operational concept of market area is richer than its strict economic counterpart discussed earlier. All the geometric and topological properties of market areas (Section Spatial Analysis) are still pertinent under the spatial interaction paradigm. The intensity of demand in and out of the market area adds an important dimension to the characterization of market areas. The principle of spatial interaction generates a pattern of decreasing demand intensity away from the firm location, the rate of which depends on the structure of transportation costs and on interfirm competition.

The spatial interaction approach to spatial market analysis recognizes that firm attractiveness may be a multifaceted notion shaped by price, service, and merchandising properties of the firm. It also recognizes that perceived attractiveness is what influences firm choices and that sociodemographics is a powerful mold of individual perceptions. The capability to segment consumers by their sociodemographic characteristics becomes handy when the study area is highly segregated socioeconomically. It is now commonplace to carry market analysis within the interactive computer environment offered by geographic information systems. Automated numerical and database manipulations provide an essential toolbox for spatially enabled market analysis, also known as 'business geographics.' This data analytical capability has dramatically changed market geographies. Rather small segments of customers living in a certain district of a city and sharing similar tastes, preferences, and aspirations can now really be identified and their demand can be met locally. As the social, cultural, and ethnic mosaic of our cities has changed and as the city's geography has morphed, so has the geography of markets and of retailing.

In contrast to other market analysis approaches, the spatial interaction framework emphasizes that location matters. The geographic space and the modalities of how one reaches one location from another can be richly portrayed in a spatial interaction model if the appropriate data are used. This approach has freed scientists from assuming that inhabited spaces are as devoid of features as the flat and uniform surface of the Euclidean space. Spatial separation between a residential neighborhood and a movie theater can be accounted for by the drive time, even as it varies with the time of the day in response to traffic conditions. In such a study, Yue et al. (2012) use fine-grained Global Positioning System taxi traces to calibrate a spatial interaction model of market area delineation. This application is in line with recent trends in spatial information analysis to rely on large and highly disaggregated data sets (so-called big data) to better contextualize the behaviors embedded in the data. Another trend in this respect is based on the recognition that space and time have substitution relationships that can be exploited to compensate deficiencies of choice options. Therefore, the ability to reach potential destinations is to be defined in the space–time context and may be advantageously extended to a hybrid space–time space (Shaw and Yu, 2009).

Concluding Remarks

Consumerism and compelling marketing practices have replaced mass merchandising with ever more finely defined customer segments with their own wants and needs. Where sale price and travel cost used to be the driving forces, markets have become more fluid, uncertain, and varied than ever before. It should not be too much of a surprise therefore that the marriage of spatial interaction and conventional, microeconomic market-area analysis has enhanced our grasp of contemporary spatial market systems. The greater propensity of firms to form spatial clusters can be ascribed to the disappearance of exclusive market areas stipulated by the spatial interaction paradigm (de Palma et al., 1985). Concomitantly, a countervailing transformation may manifest itself in the form of greater differentiation of firms from each other (Thill, 1992) to better cater to the diversity of consumer segments.

In these times where information technologies are quickly redefining the relationships between demand and supply in postmodern economies, the question naturally arises whether electronic commerce (e-commerce) will bring the demise of the notion of market area. This postulate is in line with Cairncross's 1997 provocative title 'The Death of Distance.' While no definite answer can be advanced at this time, partial arguments can be articulated as follows. As a rapidly increasing portion of postmodern economies is siphoned through e-commerce, more commerce takes on a new organizational structure wherein spatial relationships and territoriality may play a lesser role. New commercial relationships contribute to the emergence of

new geographies, namely, the virtual geography of information and communication flows on the network of computer servers, the geography of social media users, and so on. It has been argued that the notion of market area is not tied to the existence of a physical space and that it has bearing in the space framed by firm characteristics. In the same vein, the notion can be extended to the topological network of the information superhighway. Additionally, even the most optimistic projections on the expansion of e-commerce do not predict that it will entirely replace traditional commerce. Hence, in all likelihood, face-to-face commerce and associated geographic markets will subsist. This is not to say that spatially defined markets will remain unaltered by the digital revolution. Location-based services are slowly but surely leaving a mark in the market place, but they also enable new forms of selective sharing of information based on locational proximities (i.e., accessibility), thus reestablishing the importance of location and geography in human behaviors where it appeared to be receding not too long ago. If evolution of the past decade gives any indication of future trends, the notion of market area will continue evolving in response to technology-enabled practices of targeted marketing toward increasingly entwined fields of interaction.

Abstract

What determines structure and profitability across markets for goods and services? Understanding the relationship between market structure and performance is critical for determining effective economic policy governing antitrust, intellectual property, industry regulation, and international trade. Economists have analyzed these issues for many decades. An initial descriptive literature has given way to a more formalized game-theoretic approach. One stream of literature paints on a large canvas, identifying strong mechanisms that can hold across the broad run of industries. The other focuses on specific industries, building detailed models tailored to key institutional details. Both have yielded important insights and raised additional questions and directions for future research. Recent work promises to unite both streams under a common methodological framework.

Introduction

Why are some markets dominated by a handful of firms, even at a global scale, while others remain consistently fragmented? Why are some firms able to charge prices that far exceed their costs of production, while other firms can barely break even? Does competition drive firms to be more productive? Questions like these have occupied industrial organization (IO) economists – microeconomists that study markets characterized by imperfect competition – for many decades. One way of framing these questions is to focus on the connection between market structure and market performance. Do more concentrated markets facilitate greater collusion, yield higher prices, and/or experience fewer productivity gains? Can firms make strategic investments in R&D or advertising that yield market structures that are more conducive to collusion? Because economic policy is often implemented at a level that impacts many industries at the same time, it is useful to develop answers and insights that apply to the broad run of industries. At the same time, more detailed or 'local' predictions may be needed to understand, for example, the impact of a particular merger in a specific industry.

Perhaps not surprisingly, economists have approached these questions from both perspectives. Using the structure of game theory, the *bounds approach* focuses on identifying strong mechanisms that apply under the most general of conditions, while the *structural method* uses the game-theoretic structure to focus on more narrow predictions tailored to specific industries. The following short survey provides a brief overview of the evolution of these literatures. I begin with a review of an earlier descriptive literature that identified many of the key stylized facts that are still being grappled with today. I then highlight the limitations of this early analysis as identified by a more formal game-theoretic approach to modeling industrial structure. In response, two separate but complementary streams of literature have emerged. I first discuss the bounds approach, which emphasizes broad cross-sectional predictions that hold across many industries, and then the structural method, which focuses on detailed institutional settings in which stronger modeling assumptions are appropriate. I conclude with a brief summary of a recent literature that combines features of both approaches.

Definitions and Empirical Measures

To set the stage, it is useful to first provide some definitions, along with the empirical measures used to quantify both market structure and market performance. *Performance* generally refers to how competitive (or efficient) an industry is or, more broadly, how successful it is at delivering benefits to consumers. The main focus is on competition, and its connection to the profitability of firms. Competitiveness can be captured by the degree of market power, which refers to a firm's ability to set price above the cost of producing a single additional unit. A natural measure of market power is the price-cost margin $\left(p-c, \text{or } \frac{p-c}{p}\right)$. A share-weighted average of price-cost margins yields the more general Lerner index of market power for the industry as a whole, providing an overall measure of competitiveness. Although some authors prefer to calculate a rate of return on investment (to get more directly at profits), issues of measurement and interpretation can introduce significant noise into this calculation (Fisher and McGowan, 1983), leading many researchers to turn away from these and other accounting-based constructs.

Market structure refers to the identity and relative sizes of the firms that comprise an industry (and, in the case of multiproduct firms, the products they produce). Often, it can be fully captured by a list of each firm and their respective market shares (i.e., their share of total industry revenue). In industries with a large number of firms, or when relying on published summary statistics, employing a function of these shares to summarize market structure can be more practical. The most common such function is the k-firm concentration ratio, which reports the combined share of the largest k firms in the industry. Typical values of k are four and eight, though many such measures may be reported (unfortunately, the share of the largest firm is often masked for confidentiality reasons). The sum of the squared market shares, called the Herfindahl index,

provide a single measure of the *overall* structure that is often employed in merger analysis. Critically, any measure of market structure requires a careful definition of the relevant market, a task that can be complex in certain cases (e.g., does a 'smart' phone belong in the same market as a digital camera?) and plays an important role in antitrust analysis.

The Structure-Conduct-Performance Paradigm

Systematic efforts to describe the relationship between market structure and market performance began with the development of the Structure-Conduct-Performance (SCP) paradigm, a framework most closely associated with Edward Mason and Joseph Bain. Although it has been sharply critiqued in the ensuing decades, the SCP literature served to systematically identify and highlight many of the stylized facts and empirical regularities that motivate the modern, game-theoretic approach. While too vast to adequately summarize here, Schmalensee (1989) provides a comprehensive review of the SCP literature and the stylized facts it uncovered.

The SCP framework posited a one-way chain of causation running from industry structure (firm concentration) to firm conduct (pricing) to market performance (profitability, innovation). The central claim was that high concentration would lead to high prices and thus high profits. Recognizing that free entry by competing firms ought to quickly erode these profits, significant barriers to entry would then be required to maintain a concentrated structure. In his earliest work, Bain associated these entry barriers with fixed economies of scale in production (i.e., falling average costs), which could arguably be taken as exogenous to the firm's decision-making problem (i.e., predetermined). The validity of this exogeneity assumption will play a critical role in what follows. Analyzing a cross-section of US manufacturing industries, Bain (1956) documented a significant correlation between scale economies and concentration, consistent with the framework's predictions. The rapid increase in available data sets facilitated the production of many such studies throughout the 1960s and 1970s.

At the same time, Bain and later contributors to the SCP literature identified other industries that did not feature these production economies yet still remained concentrated due to intensive investment in advertising and/or research and development (R&D). For example, the soft drink industry has remained remarkably concentrated for many decades despite little required investment in fixed costs of production. Instead, there is an intense rivalry in advertising outlays required to effectively build and maintain a national brand. The shift of focus to these new sources of scale economies led to two problems. First, the empirical results here were more mixed, particularly in the case of R&D, which exhibited little systematic correlation with market structure. More critically, many economists argued that advertising and R&D should more appropriately be thought of as decision variables of the firm, not as predetermined features of the business environment. Addressing this concern is a key focus of the modern, game-theoretic literature.

The SCP literature was also successful in identifying a second strong empirical regularity: the impact of increased competition on prices (and price-cost margins). The hypothesis that a fall in market concentration leads to a fall in prices and price-cost margins found strong empirical support, as well as solid theoretical underpinnings. This conjecture provides another important jumping off point for the more recent literature. Unfortunately, the relationship between market structure and *profitability* proved much more vexing and the empirical evidence decidedly mixed. Measurement and interpretation issues plagued the accounting numbers used to quantify various measures of profit or rate of return (Fisher and McGowan, 1983). Perhaps more damning were issues of interpretation.

The SCP approach takes structure as given, implying that markets that are both concentrated and profitable must be in some way collusive or noncompetitive. An alternative viewpoint, most closely associated with economists from the Chicago School (Harold Demsetz and Sam Peltzman), reverses the order. To understand their concern, consider two industries, one in which all firms share the same capabilities and a second where firms exhibit sharp differences in efficiency. The industry with heterogeneous firms will likely end up more concentrated – with the efficient firms garnering a larger market share – and more profitable (at least for the leading firms, since free entry will only drive the profits of the marginal firm(s) to zero). However, in this case, the interpretation is clearly pro-competitive. Moreover, the relevant empirical evidence has tended to support the efficiency argument.

The Demsetz critique was emblematic of a deeper conceptual problem with the SCP framework. The assumption of a one-way chain of causation from structure to performance ignores the possibility that, for example, perceptions of conduct and performance might instead drive the entry decisions that determine structure. Consider a market in which firms perceive a fierce degree of price competition upon entry. Anticipating a limited scope for sustained profitability, a smaller number of firms might enter than would have had they perceived a more collusive economic environment (e.g., accommodation by a well-functioning cartel). Thus, policies that foster competition (e.g., tougher antitrust policy) might actually lead to *more* concentrated market structures. This surprising conclusion is a central point of the bounds approach discussed below. Broadly speaking, while the SCP approach was successful in identifying a large number of empirical regularities, it failed to address the complex role of strategic interaction in determining firm conduct. These interactions play a key role in the game-theoretic approach discussed next.

The Game-Theoretic Approach to Market Structure

The formalism of game theory provided IO economists with a rigorous framework with which to examine the subtle interconnections between firm strategies, market structure, and market outcomes. Additional motivation for differences in firm shares and fortunes were found in the strategic asymmetries arising from the opportunity to move first, the ability to 'learn by doing', or the incentive to exploit 'network effects' across interconnected markets. However, more than a decade of careful research brought the sobering conclusion that robust results that could apply to the broad range of industries were

few and far between. Seemingly arbitrary features of the game setup often lead to vastly different equilibrium outcomes. Critically, many results necessarily turn on such difficult to proxy factors as a firm's beliefs about its rivals' actions or the exact timing of investment decisions, as well as other inherently unobservable constructs such as the number and identities of potential entrants. On the one hand, the flexibility of the game-theoretic framework allows it to rationalize a wide spectrum of outcomes. On the other, a wide range of models can explain the same specific outcome, undermining a key assumption in most statistical models (a one-to-one mapping from parameters to outcomes) and thereby complicating statistical inference. IO economists faced a trade-off between constructing highly specialized models tailored to a particular setting, or opting for less-sharp predictions that might hold across a broad range of settings.

It is important to note that this ambiguity is a natural feature of the economic setting, not a failure of the game-theoretic approach. Realistic games often have multiple equilibria, arising from different beliefs or the vagaries of implicit coordination. More generally, the outcomes of formal models often depend delicately on assumptions that are difficult to observe or verify (e.g., Do players move simultaneously or sequentially? Is competition best modeled as occurring in prices or quantities?). This lack of information is an intrinsic feature of the economic environment. Many of the constructs that we would like to condition on (e.g., costs) are either unobserved or challenging to control for. In response, the modern game-theoretic empirical literature has moved in two separate, yet complementary directions. One embraces the ambiguity; the other places structure upon it.

The first, which is now known as the bounds approach, continues the SCP tradition in seeking to identify predictions that hold across a broad range of industries. To do so, it favors mechanisms that are robust to a wide range of modeling choices and depend only on observable features of the economic environment. The second approach, typically referred to as the structural method, focuses instead on single industries in isolation, where more specific modeling assumptions can be brought to bear, allowing unobserved elements to either be recovered from the assumptions of the model or controlled for in the statistical design. The most recent work combines elements of both.

The Bounds Approach

The bounds approach is most closely associated with the seminal work of John Sutton (1991, 1998), his students, and coauthors. This section draws heavily on Sutton's exposition. The goal of the bounds literature is to identify a number of 'strong mechanisms' that characterize equilibrium outcomes across a broad range of industry settings. The idea is to invoke as few assumptions as possible, building only from the most strongly confirmed empirical regularities, and deriving testable implications that hold irrespective of arbitrary or difficult-to-verify modeling choices. In practice, this involves placing restrictions on outcomes, rather than strategies. By constructing, painting on so large a canvas will limit the sharpness of predictions.

Sutton starts from a general game-theoretic setup in which a large number of firms (beginning life as potential entrants to an industry) compete in a series of stages, culminating in a final, product-market competition stage that determines industry and firm profits. In the simplest version, there are just two stages: an entry/investment stage and a price competition stage. Firms are strategic and forward-looking in their choices and investments, anticipating how their actions (and those of their rivals) will influence market outcomes. Unlike the SCP framework, entry is endogenous. For example, firms that do not foresee earning nonnegative returns in the product market will choose not to enter, reflecting a key component of the Demsetz viewpoint. In this setting, the outcomes that may survive as equilibria must satisfy two fundamental properties: *viability* and *stability*. Viability ensures that all firms that choose to enter the industry expect to earn nonnegative profits. This condition eliminates cases in which all firms choose to enter. Stability requires that any firm that chose not to enter expected to lose money (i.e., earn negative profits). Note that these are standard properties that any pure strategy, Nash equilibrium must satisfy within this class of models.

Based on these two properties, Sutton establishes a series of strong results or 'robust mechanisms' characterizing equilibrium market structure. The first applies to industries in which advertising and R&D play no major role in competition (i.e., the types of industries with which Bain was originally concerned). These are referred to as exogenous sunk cost markets or Type 1 industries. What happens to market structure as market size expands in these settings? Sutton shows that, in these exogenous sunk cost markets, as market size increases, the minimum level of concentration that can be supported as an equilibrium configuration decreases asymptotically to zero. Phrased differently, the *lower bound* to concentration decreases to zero as market size expands. Note that this does not imply that every market will experience a monotonic decrease in concentration as market size expands – this is a bound not a functional relationship. In some cases, markets may remain concentrated indefinitely. This lack of precision is a product of the theory's breadth: although we can construct examples in which the profitable opportunities that arise as market size expands are systematically capture by the largest firms, we cannot *rule out* equilibria in which markets become more fragmented as markets grow in size. For this reason, this is sometimes called a 'fragmentation' result. Note that we will find the opposite conclusion when we shift attention to advertising and R&D intensive industries below.

Sutton's second 'robust mechanism' concerns the relationship between the shape and position of this lower bound and the degree or 'toughness' of competition that prevails in a given market. The degree of competition determines the shape of the function that aggregates the decisions made by all firms in the investment stage(s) and produces the vector of profits arising in the competition stage. This shape is influenced by decisions such as whether to model competition as taking place in quantities (so-called Cournot competition, which is considered somewhat collusive) or prices (so-called Bertrand competition, which is viewed as more competitive) and environmental factors like the degree of antitrust enforcement and the ease

of transportation. What happens to concentration or, more precisely, the lower bound to concentration, as competition becomes tougher? Consider a shift from a more collusive setting to one that is more competitive. For example, suppose the regulating authority increases the penalty (or strengthens enforcement) associated with anticartel laws. This change would imply an increase in the toughness of competition, as firms would presumably now find it more difficult to collude. Sutton's second result establishes that an increase in the toughness of price competition will lead to an upward shift in the lower bound to concentration, although the lower bound will still tend toward zero as market size expands. This shift is driven by the viability condition noted above: a return to equilibrium will require some firms to exit or consolidate, thereby raising the equilibrium level of concentration for a given market size. Note that this has important policy implications: efforts to increase competition can lead to a more concentrated market structure. This is likely not what one might first expect and illustrates the power of the game-theoretic perspective.

Both results have garnered strong empirical support. Sutton (1991) provides a wide-ranging, multi-industry, cross-national analysis that includes both formal statistical tests and compelling case studies. More recently, Sutton (2007) provides a comprehensive overview of the related literature, which includes many empirical studies that complement the bounds approach.

Perhaps the most provocative of Sutton's results concerns those industries in which advertising or R&D plays a critical role. Owing to the strategic nature of these investments, these 'Type 2' industries are referred to as *endogenous* sunk cost markets. In these settings, Sutton instead finds that concentration is bounded below, breaking the fragmentation result described above. As market size expands, the share of the largest firm remains strictly positive. The formal result can be summarized as follows. Let $S\pi$ denote the profit earned in the final stage of competition, where S represents the size of the market and π a function capturing all previous investment and pricing decisions. Assuming marginal costs are flat and markets increase in size through successive replication (meaning larger markets are no more heterogeneous than their smaller counterparts), suppose that for some constants $a > 0$ and $k > 0$, a firm that spends k times as much on fixed costs as any rival can earn at least aS in the final stage, there then exists a lower bound to concentration that is independent of the size of the market. Thus, unlike the previous exogenous fixed cost case, the importance of R&D or advertising places a sharp limit on the structure of markets that can survive in equilibrium. Fragmentation cannot occur here. Larger markets are still more profitable than small, but as market size expands the incentive to increase the level of fixed investments rises accordingly. In particular, larger markets will induce greater investment by at least some firms, eliminating the indefinite fall in concentration observed in the Type 1 markets. Sutton therefore provides a compelling reason for why some industries are consistently dominated by a handful of firms: the escalating nature of their required sunk investments. Sutton (1991) provides strong empirical support for this nonconvergence result across a broad range of industries.

Applications and Extensions of the Bounds Approach

Several authors have applied Sutton's framework in a variety of institutional settings, often extending the scope of what are considered endogenous sunk investments. For example, Ellickson (2007) uses the bounds approach to analyze competition in the US supermarket industry. While relatively unconcentrated at the national level, the grocery industry is dominated at the local (city) level by 3–4 chain firms, an empirical regularity that holds for geographic markets both large and small. While R&D and advertising play almost no role in this industry, Ellickson argues that supermarkets invest competitively in information technology aimed at increasing the number of products offered in each store. These investments limit the number of firms that can profitably compete. A key challenge is identifying independent markets of varying size with which to test this nonconvergence result. Ellickson argues that, on the supply side, relatively independent grocery markets can be defined at the level of the distribution center, and uses variation in the size of these 'distribution markets' to identify the lower bound to concentration. He finds that the share of the largest firm is bounded below at a limiting level of over 12% while, in a comparison industry in which costs are exogenous (barber shops and hair salons), that level falls to under 0.5%.

Sutton recognized the role of independent submarkets in establishing robust predictions. The challenge is particularly acute in the case of R&D, where intense spending along a narrow research trajectory can lead to both high levels of investment and deceptively low levels of market concentration in industries where markets are defined too broadly. In Sutton (1998), he expands his earlier analysis to include settings in which R&D leads to multiple, independent trajectories. Once again taking a bounds approach, he provides a method for identifying the types of R&D intensive industries that will remain persistently concentrated. Finally, he also develops a bound prediction that applies to the long-standing debate over the size distribution of firms, providing a game-theoretic rational for what was historically a purely statistical literature.

Structural Methods

Reacting to both the inherent ambiguities embedded in the game-theoretic approach and the limitations on what we can clearly observe and quantify as empirical researchers, Sutton's bounds approach is based on making as few assumptions as possible. In contrast, the more dominant structural approach to empirical analysis adopts a more focused perspective, emphasizing single industry settings in which stronger assumptions can be employed and (ideally) validated. In so doing, it can deliver far more precise predictions. It also makes explicit the assumptions underlying identification of causal effects, allowing the reader to judge for themselves the appropriateness of various modeling choices. Furthermore, by uncovering the economic primitives that drive agents' strategic choices, alternative (counterfactual) scenarios can be evaluated, including large changes to economic policy that may be well outside what is observed in the data. Of course, the validity of these predictions relies on the realism of the

proposed model, which must be carefully tailored to the specific institutional setting. Consequently, the structural approach focuses expressly on specific industries, where detailed data and institutional knowledge can mitigate some of the concerns regarding unobservable, or poorly measured, covariates and justify the stronger assumptions needed to sharpen our predictions. When carefully executed, structural methods can yield insights that are not available from simple descriptive analysis.

While the earliest structural work attempted to estimate a 'conduct parameter' characterizing firm behavior, the modern approach assumes a form of conduct and uses detailed modeling assumptions to recover difficult-to-measure constructs like the variable and fixed costs of production. For example, to evaluate a merger in the soft drink industry, a detailed demand system would be estimated. By assuming a form particular of conduct (e.g., Nash in prices competition among differentiated firms), estimates of the variable cost of production can be recovered (eliminating the need to rely on the accounting measures criticized earlier). With these estimates in hand, a fully specified model of competition can then be used to simulate outcomes under different ownership structures, quantifying the impact on both consumers and producers (e.g., Nevo, 2000). Thus, the impact of the merger can be evaluated prior to its consummation, thereby guiding optimal policy decisions. The entry of new products or changes in other regulatory policies can be analyzed similarly. These methods now play a key role in merger analysis.

While structural methods have been used to address a broad range of questions in IO, the two areas closest in spirit to the market structure and performance agenda are the 'static entry' literature and the recent work on dynamic games. Both streams of literature include a substantial methodological component, as researchers work through the implications that the aforementioned informational incompleteness has on statistical inference, while tackling the daunting computational burden of estimating multiagent models. In keeping with the applied focus of this overview, I will emphasize the more policy-related issues addressed.

The static entry literature began with the seminal work of Bresnahan and Reiss (1990), which focused on the strategic entry decisions of small retail firms in isolated rural markets (the emphasis on isolated markets helps address the issue of market definition noted earlier). Bresnahan and Reiss examined the relationship between market size and the number of entrants to the market, attempting to isolate the impact of price competition on firm profits. They reasoned that if total industry profits decrease in the number of entrants and firms must pay a fixed and sunk cost to enter the market, then the market size that could accommodate two firms would need to be more than twice as large as a market that could only accommodate one (holding other drivers of profitability fixed). In particular, if competition drives down profits, the number of firms that enter a market should grow less than proportionately with the size of that market. Note that this provides an indirect test of the price-competition mechanism identified under the SCP paradigm and taken as a primitive in the bounds approach.

By focusing on the number of entrants (as opposed to their identities), they were also able to finesse some issues of incompleteness associated with multiple equilibria. In a series of papers, Bresnahan and Reiss documented a strong price-competition effect that tapered off once 3–5 firms were present in a market. This tapering off also provides support for the intuition that collusive behavior may be harder to sustain with a larger number of participants, a common assumption in many treatments of tacit collusion. Recognizing that the less than proportionate increase in firms might instead reflect a version of the Demsetz critique, Berry (1992) extended the Bresnahan and Reiss approach to accommodate heterogeneity in firms. Berry reasoned that if the more efficient firms enter first, it would then make sense that later entrants would require a proportionately larger market (greater demand) over which to spread their relatively higher cost outlays. Focusing on the airline industry, Berry continued to find a strong price-competition effect despite these differences in efficiency. However, in keeping with a central theme of the bounds approach, this sharper prediction required a stronger assumption: a specific mechanism for selecting among equilibria (with sharp differences across firms, the number of entrants may no longer be unique as it was with Bresnahan and Reiss). Subsequent authors have extended the framework to include additional sources of product differentiation (Mazzeo, 2002), network economies (Jia, 2008), and alternative information structures (Seim, 2006).

Up to now, the focus has been entirely on cross-sectional implications of what are mostly static models of firm competition and industry structure. Clearly, most industries are dynamic, with structures that continue to evolve over time. Concepts like 'learning by doing' and price skimming are inherently dynamic, while the payoffs to research and development are often realized several years in the future. Fortunately, in the 1970s and 1980s, detailed firm-level census data increasingly became available, allowing researchers to document industry evolution at an extremely disaggregated level. The nature of this evolution has important implications for issues like first mover advantages, industry shakeouts, learning, and innovation. What emerged was clear evidence of heterogeneity across both firms and industries, with entry and exit often occurring simultaneously. To begin to address these issues, Ariel Pakes and his coauthors have developed a flexible framework for analyzing firm dynamics from both a theoretical and empirical perspective. This framework, originally formulated by Ericson and Pakes (1995) but extended in many directions by subsequent authors, can accommodate simultaneous entry and exit, strategic investment, imperfect competition, and both firm- and market-level heterogeneity. While this research agenda is still in its early stages, its application has blossomed in the past few years due to recent advances in estimation and computational techniques (Doraszelski and Pakes, 2007).

Goettler and Gordon (2011) provide a nice illustration of how this framework can be applied to examine the relationship between market structure and performance. Up to now, we have emphasized the impact of market structure on firm profits, but structure should also influence other outcomes like innovation and productivity. In particular, we might ask if competition spurs productivity? Or does a monopolist, who is in an ideal position to fully appropriate the fruits of their labor, have greater incentives to innovate? Goettler and Gordon

develop a structural model of competition between Intel and AMD in the production of microchips (CPUs). Entering a long-standing debate between adherents of the viewpoints offered by Kenneth Arrow and Joseph Schumpeter, the authors ask what would happen to innovation (and prices) if AMD were to cease to exist. Consistent with the Schumpeter argument, they find that the rate of innovation would be 4.2% higher in AMD's absence. However, consumer surplus would also fall by 4.2% due to the higher prices that would be charged by Intel. Whether these insights might apply in other settings is an open question, but a similar approach could be used to analyze other industries.

A Structural Bounds Literature

Both the bounds and structural IO literature are motivated by the twin limitations of our ability to predict outcomes (via formal game-theoretic models) and the degree to which we observe all the relevant institutional details and statistical covariates that drive observed structure. This model 'incompleteness' arises from limited information on the part of the researcher regarding the correct modeling assumptions, the relevant covariates to include in a regression, the underlying equilibrium selection mechanism, and the key institutional details that govern firm behavior. As structural researchers seek to limit the number of assumptions they must invoke to conduct analysis, the two strands of literature start to merge. In particular, the pioneering work of Charles Manski and Elie Tamer regarding the econometric treatment of such incomplete models is now being used to tackle questions of market structure and performance. However, rather than starting from the most general setting (a la Sutton), the approach here is to begin from the particular and move to the more general. For example, in an extension of the Berry model of airline competition, Ciliberto and Tamer (2009) are able to relax the requirement of an explicit equilibrium selection mechanism in a model with heterogeneous firms, delivering on the promise of more detailed insights with fewer assumptions. Similar methods might relax the requirements on assumed conduct even further (to allow bargaining or matching models to be considered as well).

Conclusions

The relationship between market structure and market performance has occupied IO economists for several decades. Providing concrete insights is important for determining effective policy toward antitrust, intellectual property, regulation, and international trade. An initial descriptive literature has given way to a more formalized game-theoretic approach to tackling these questions. One stream of literature paints on a large canvas, identifying strong mechanisms that can hold across the broad run of industries. The other focuses on the more narrow picture, building detailed models tailored to specific industrial contexts. Both have yielded important insights and raised additional questions and directions for future research. Recent work promises to unite both streams under a common methodological framework.

Abstract

Marketing strategies are reviewed both in an external (i.e., 'Market Power School') and internal (i.e., 'Resource-based View') perspective. Focus will be put on marketing strategies based on market-driving capabilities and resources. A model of competitive strategies will then be presented in a circular perspective, considering the shifting nature of what are called movement, imitation, and position games.

Introduction

Marketing strategies pursued by firms are aimed at obtaining a sustainable competitive advantage over competitors. In a marketing perspective, firms obtain a competitive advantage when they are able to identify, create, and communicate reasons of preference for their customers, with respect to their competitors.

In this article, marketing strategies will be reviewed both in an external and internal perspective. Focus will be put on marketing strategies based on market-driving capabilities and resources. A model of competitive strategies will then be presented in a circular perspective, considering the shifting nature of movement, imitation, and position games. Some final points about marketing strategies in the third millennium will be presented, with the proposition of a new, proactive firm, able to compete in different games, with different strategies and weapons, like trust, creativity, sensing, integration, and networking capabilities.

Marketing Strategies in an External and Internal Perspective

Marketing strategies can be viewed in two different ways: (1) with an external emphasis, typical of the 'Market Power School,' which dominated the 1980s; this school draws on the Harvard tradition (Mason, 1939; Bain, 1956) in industrial economics studies; however, Porter (1980, 1985) is the most important author within this stream of thought and (2) with an internal emphasis, typical of the Resource-based View of the Strategy, which dominated from the 1990s. Authors like Wernerfelt (1984), Rumelt (1984, 1987), Barney (1986), Dierickx and Cool (1989), Itami (1987), Grant (1991), Peteraf (1993), and Prahalad and Hamel (1990, 1994) have been among the most important contributors within this stream of thought.

1. The 'Market Power School' puts its emphasis on the analysis of the existing environment, following the 'Structure-Conduct-Performance' paradigm of industrial organization. The normative prescriptions of the Market Power School, particularly the three generic strategies suggested by Porter (1980, 1985) – differentiation, cost leadership, and niche strategies of focalization – depend on the external analysis of the environment, conducted mainly with the five-forces model. The five-forces model is an analytical tool developed by Porter (1980, 1985) which helps to individuate the attractiveness of an industry, by analyzing not only the competitors actually in the arena, but also the forces of the potential entrants, the producers of substitutes, and the influences of customers and suppliers. Therefore, the 'Market Power School' considers strategy primarily as positioning a firm in a given industry context; the focus is on the external analysis of the existing industry and on its attractiveness. The strategic process should determine a 'fit' between the given distinctive strengths of a firm and the given opportunities offered by the external environment.

In synthesis, the Market Power School considers the general strategic process, at the corporate level, as the allocation of the right mix of resources to the various Strategic Business Units, adopting a financial portfolio view, and the competitive and marketing strategies, at the business level, adopting a product-based view of competition.

2. The Resource-based View of the Strategy, rather than on the external environment, puts its emphasis on the unique endowment of resources, assets, competencies, and capabilities of each firm. By creating and continuously incrementing its resource endowment, a firm becomes different from another. So the unique endowment of each firm is at the roots of its competitive advantage, whose sustainability is higher, the higher are the barriers raised to imitability. Marketing strategies are not concerned with the exploitation of the existing resources, but with the continuous internal commitment to increase the resource endowment. A clear example of a resource that should be increased, and not just exploited, is brand equity (Aaker, 1984, 1991).

Resources may be either tangible or intangible; it has been widely recognized that marketing strategies based on intangible resources generate hard to imitate competitive advantages. Typical marketing resources are trust and knowledge; both are intangible and strongly linked with customer conviction (Reicheld, 2003, 2006), which is the beginning and the end of every marketing strategy. At the beginning, customer conviction is the key because a delighted customer, promoting our value proposition, is the very aim of any successful growth strategy.

At the end, it is the most important result of each marketing strategy, because the long-term survival of a firm depends on the level of satisfaction, loyalty, and trust of its customers. So analysis, measurement, and improvement of the customer experience are among the most important activities for marketing strategies in a resource-based perspective (Valdani, 2009).

Marketing Strategies in a Resource-Based-View Perspective

In recent years, firms tend to be living in a new competitive landscape, which is characterized by structural changes mostly related to the new digital environment. This leads to a tremendous empowerment of the customer, as well as to new opportunities for collaboration within the entire value system of the company, from suppliers to business partners.

At the same time, these changes inevitably lead to a dramatic increase of the competitive pressure, continuing a trend started in the 1990s and effectively described by the expression 'hypercompetition' (D'Aveni, 1994; Valdani, 1995, 2000).

As a matter of fact, in the current turbulent environment, normative prescriptions based on static industry analysis tend to become useless. As Grant (2010) puts it, when the external environment is in a state of flux, the firm's own resources and capabilities may be a much more stable basis on which to define its identity. In the resource-based perspective, marketing strategies recognize the logical and temporal dominance of resources upon products. Products are considered only as the expression of the internal resources of the firm. Moreover, resources are not product-specific, but they can lead to the achievement of competitive advantage in a wide range of products and services. For example, the exceptional resources and capabilities of Apple, in terms of market sensing, customer experience, and brand identity, allowed this company to replicate and enjoy a competitive advantage in a broad set of new markets, beyond the traditional computing battlefield.

In this perspective, it is possible to state that firms need to adopt a proactive approach to their marketing strategies, leveraging their market-driving capabilities in order to reach a double aim: to manage the present and to prepare for the future at the same time (Abell, 1993; Valdani and Arbore, 2012). This is a so-called dual strategy. To manage the present means developing capabilities of relationship management, competitive intelligence, and process reengineering in a customer-centered perspective. To prepare for the future means developing the managerial capabilities of destroying the existing common wisdom, to imagine, enact, and create a new competitive environment, regenerating strategies and reinventing industries and their borders.

Marketing Strategies in a Circular Model

It is possible to describe the marketing strategies of a firm by adopting the circular model described in Figure 1. The model shows the three possible states of nature of the competitive arena. They are: the game of position, the game of movement, and the game of imitation.

Figure 1 Marketing strategies in a circular perspective. Adapted from Valdani, E., Arbore, A., 2012. Competitive Strategies: Managing the Present and Planning the Future. Palgrave Macmillan, Hampshire, England.

Marketing Strategies in the Game of Position

During a game of position, the environment is quite stable, the product life cycle is generally in its maturity phase, and both customer needs and competitors are well defined. General marketing logics in a game of position are those of market sharing, aimed at increasing a firm's market share by reducing the competitors' one: aggressive marketing spending or pricing strategies are very important in these conditions. This, of course, makes the game of position a 'win–lose' scenario.

On 9 July 2007, for example, Sony Corporation issued a press release announcing that it was slashing the PlayStation3 price tag by $100, which was 17% less than the introductory price set in November 2006. At the same time, the company publicized the launch of a model with more memory at the previous price. The same day at a press conference in Tokyo, a Microsoft executive hastened to state that the company would not lower Xbox 360 prices. Nonetheless, on 7 Aug 2007 the Redmond firm announced a $50 price cut on the US market, to be followed two weeks later by a €50 reduction in Europe (approximately 13%). Similar moves by both companies would replay in October, November, and December. And again until the launch of the new versions. The strategic evolution in this competitive arena suggests that Sony and Microsoft were then playing what we called a Game of Position. These maneuvers typically cause a drop in profitability, since direct, frontal competition forces the companies to offer more and more for less.

Here the firms must effectively and efficiently manage all their processes and their offering in terms of brand, price, communication, promotion and distribution policies, potentially to the ultimate point of market commoditization. In sum, since the sources of the competitive advantage in a Game of

Position are well-known, any potential advantage is often a negligible one: it is all about pitting strength against strength. As a result, in sectors that enjoy no legal barriers to protect from competition, this scenario tends to evolve toward a so-called final frontier of value (D'Aveni, 1994), that is, a situation derived from the notion of perfect competition found in classic economic theory, where long-term profits are nil (Figure 2).

Marketing Strategies in the Game of Movement

In order to avoid the evolution to the 'final frontier of value,' firms pursue strategies of market regeneration and market creation, that is, what we call games of movement. In a proactive perspective, these companies increment, leverage, and stretch their market-driving capabilities and resources. By doing so, they create new markets or reconfigure radically the existing ones. These maneuvers usually require also networking strategies: in fact, a game of movement is often successful only in a coevolutionary perspective, putting together resources and competences of many companies.

"Give me a place to stand on, and I will move the Earth" said Archimedes. To initiate a Game of Movement, the "places to stand on" are as many as marketing managers can imagine. Indeed, disruptive levers are not exclusively or necessarily related to technology or research and development, as widely acknowledged and accepted evidence reminds us. For example, the Netflix's game of movement, which defeated Blockbuster, was just based on *different* channels (the Internet and the Postal service) and a *different* pricing scheme (monthly flat fee, instead of pay-per-rent). It is not anymore about doing more for less, like in the game of position, but doing things a different way. This is about winning without fighting, that is, avoiding a direct attack. This is the story of companies introducing new value propositions, or even new business models, like Ikea, Zara and low cost airlines.

The specificity of the game of Movement requires an array of competitive weapons, based on new knowledge generation, information, creativity, and firm competency integration at various levels: inside and outside the organization, and more and more often, also outside the borders of one's industry. The successful story of functional foods like Danacol (Danone's dairy drink that lowers cholesterol) is an example of this kind: a food company exploring the borders of the pharmaceutical industry.

Figure 2 The ultimate value frontier. Reproduced from Valdani, E., 1995. Marketing Strategico. Etas Libri, Milan, Italy.

The arsenal of new competitive weapons is vital for developing, applying and disseminating innovation, in order to educate the market about innovation, to develop industrial infrastructure, to set new standards, and to make a quick entrance or exit from any given market. Last, but not least, these strategies require the ability of a firm to overcome important barriers to innovation, both externally (i.e., customer inertia) and internally (i.e., managerial inertia and technical specialization).

Marketing Strategies in the Game of Imitation

Successful innovations are typically followed by imitation. Follower firms, pursuing imitation strategies, transform a game of movement into a game of imitation. PlayStation Move and Microsoft Kinect, for example, are just the answers to the successful game of movement started by Nintendo Wii, with its innovative controllers.

To win the game of Imitation, companies must arm themselves with the ability to quickly learn what they need to know to follow the innovator, and to tap a stock of resources that is up to the task. At one end of the spectrum, imitation can produce an exact copy (see the capsule controversy for Nespresso espresso makers between Sara Lee and Nestlé). At the opposite end, imitation can be incremental, as in the Microsoft Excel worksheet, an incremental imitation of the pioneering Lotus 1,2,3. In this case, the imitation is about "doing the same things better" rather than simply "doing the same things the same way." Finally, if the original game of movement opened a completely new market, the first mover could actually welcome imitation: in fact, imitating companies would increase the overall marketing and communication efforts to support the growth of the industry.

Referring back to our previous example, by overturning existing orthodoxies the first PlayStation started a successful game of Movement. Soon, other companies followed this same strategy with the game of Imitation, starting with Microsoft. In a few years' time, with PS3 and Xbox 360 versions, the two rivals found themselves in the midst of a brutal position game, in other words, a direct, head-to-head battle once again.

Summing up, the duration of our circular model does not depend solely on the scope of innovation, but also on other players' action and reaction time, that is, again, on firms' competences and resources.

Conclusions: Marketing Strategies in the New Millennium

In the third millennium firms must be able to evolve from an era of hypercompetition to one of imagination.

Marketing strategies in an era of imagination are successful only if firms:

1. adopt a resource-based perspective;
2. focus on customer's experience, pursuing customer loyalty through 'customer's delight,' that is, exceeding customer expectations;

3. continuously regenerate their stock of market-driving capabilities, in order to avoid the trap of the 'final frontier of value' and shift continuously from games of position to games of movement;
4. coevolve with other firms, institutions, and customers, networking with them using the tremendous potentials of the new digital environments.

In order to win the competitive games of the third millennium, firms must develop marketing strategies using weapons completely different from the past. These new weapons are intangible resources and capabilities like trust, identity-signaling, creativity, integration, and networking abilities. Obviously, new weapons can only be managed by new warriors, that is, new proactive firms able to do the following:

- to deal with events and consequences of events that are yet to occur, as did Toyota when it successfully launched the Prius as far back as 1997, when ecofriendly issues were still far in the future;
- to plan for the future while governing the present, as do the most farsighted petroleum companies, which are working to reinvest today's profits from black gold to create and quickly develop new competencies in new markets;
- to redefine the destiny of the industry where they operate, as did Starbucks with its coffee shops;
- to discover new solutions to customer needs, by thinking out of the box, beyond the short-term and beyond tradition, as did Gore-Tex with fabrics that are both waterproof and 'breathable' at the same time;
- to create value by nurturing entrepreneurial spirit, teamwork, and the discipline of creativity, as does 3M, by continuously launching an amazing number of new products;
- to learn the art of coevolution, as does Apple, which owes its success to an impressive network of partners and application developers, together with customers in love with the brand;
- to reinvent itself and its markets, as Google is striving to do by turning the online search sector into an infinite editorial and advertising market.

All in all, marketing strategies will recognize the circular nature of competition: a never-ending challenge.

Markets: Anthropological Aspects

Abstract

Anthropological perspectives on markets, both in historical and contemporary societies, focus on the varied institutional, political, social, and cultural forces that create and sustain market activity, and the ways in which economic life itself is inherently embedded in social and cultural relationships, that are often ignored in conventional economic analyses of market behavior. Anthropological interests in markets, often pursued through ethnographic research, examine commonalities in the principles and practices of exchange in subsistence and peasant societies as well as in centers of advanced capitalist finance. At the same time, questions about the nature of exchange and markets in societies at varied levels of complexity link ethnographic concerns with contemporary markets to historical interest in the development of markets and their impact on social and cultural development.

Markets are so routinely regarded as fundamentally economic institutions that long-standing and quite varied anthropological perspectives on them are often overlooked. Anthropological attention focuses on patterns of individual and small-group exchange relationships within specific markets, on institutional structures that organize markets, and on the social, political, and spatial hierarchies through which markets link social classes, ethnic groups, or regional societies into larger systems. Anthropological studies of markets analyze them as nodes of complex social processes and generators of cultural activity as well as realms for economic exchange. Anthropologists' interests in markets, therefore, are partially distinct from – although certainly overlapping with – the concerns of economists.

Markets and Marketplaces

The term 'market' is inherently ambiguous. Abstractly, 'market' refers to exchange organized around principles such as 'price' or 'supply-and-demand.' 'Market' may also refer to specific social relationships and frameworks through which economic transactions take place. Markets, in the first sense, are networks of economic processes and transactions which may occur without specific locations or spatial boundaries for the transactional universe. In the second sense, markets are social institutions, often located in geographically distinct places, which encompass specific social, legal, and political processes that enable economic transactions, but also extend far beyond them. Plattner (1989) makes a useful distinction:

> 'market' [is] the social institution of exchanges where prices or exchange equivalencies exist. 'Marketplace' refers to these interactions in a customary time and place. … A market can exist without being localized in a marketplace, but it is hard to imagine a marketplace without some sort of institutions governing exchanges. (p. 171)

Marketplaces embody a localized set of social institutions, social actors, property rights, products, transactional relationships, trade practices, and cultural meanings framed by a wide variety of factors including, but not limited to, 'purely economic' or 'market' forces. Of course, anthropological analyses of markets in the first sense are often ethnographically focused on marketplaces in the second sense.

Anthropological approaches to markets sometimes focus on the formal properties of exchange systems as frameworks for organizing behavior, relying on quantitative analyses of exchange relationships. However, anthropologists generally place such analyses within wider ethnographic contexts that see marketplaces as specific locations and social frameworks, characterized not only by economic exchanges in and among them, but also by their equally vital roles as arenas for cultural activity and political expression, nodes in flows of information, landmarks of historical and ritual significance, and centers of civic participation where diverse social, economic, ethnic, and cultural groups combine, collide, cooperate, collude, compete, and clash. Anthropological and sociological analyses emphasize this 'embeddedness' of markets in ongoing patterns of social organization and cultural meaning (Polanyi et al., 1957; Granovetter, 1985); that is, economic behavior is not analyzed as an autonomous sphere of human activity, but as inseparably intertwined with a wide variety of social, political, ritual, and other cultural behaviors, institutions, and beliefs.

Marketplaces as Ethnographic Sites

Marketplaces vary enormously. They differ according to the local, regional, or global scope of production, distribution, or consumption of the goods and services they trade. Retail and wholesale markets are structured quite differently around the distinct activities and social roles of consumers, producers, and traders. Some markets handle physical commodities; others trade intangible financial assets. Many marketplaces are permanent, but in some societies markets are periodic, held at regular or irregular intervals, sometimes as one stop along regional circuits for peddlers who visit specific sites on a fixed cycle. (The tiny handful of ethnographic studies of markets listed in the bibliography give only a glimpse of the wide

variety of anthropological analyses of markets, their internal structures, and their wider social and cultural contexts: e.g., Acheson, Bestor, Bohannan, Clark, Cohen, Geertz, Hertz, Meillassoux, Mintz, Polanyi, Plattner, Roseberry, Skinner, Smith, Trager.)

Many small-scale markets are socially embedded in communities, where producers and consumers deal face-to-face over the vegetables, chickens, or bolts of cloth that are the stuff of daily life, whether in a peasant community, an urban bazaar, or a farmer's market in a middle-class suburb. Local markets, as well as much more specialized ones such as urban wholesale markets of professional traders, are often organized around complex, multistranded relationships that intertwine gender, ethnicity, class, and kinship, as well as economic role.

Other very different kinds of markets (not marketplaces) embody diffuse, impersonal (and perhaps anonymous) ties among trade partners, such as in 'spot markets' where economic actors interact only through a one-time transaction, as in many real estate markets, labor markets, and global commodity markets for things such as sugar, coffee, or rubber.

Long-distance trade – both in exotic products and mundane commodities – may pass through highly specialized marketplaces that coordinate a regional or a global industry, such as Dutch flower auctions. Some long-distance markets are organized around small tightly knit communities of professional traders who transact business within networks of trust built on ethnic solidarity, such as New York's diamond exchanges or Ibadan's Hausa traders.

Markets exist along continua between the most informal sectors of society and the most highly regulated. Some markets are organized through informal or quasi-formal institutions (open and above board, but outside the realm of legal or political attention), while others are 'gray,' 'black,' or entirely illegal. Other specialized markets for professional traders are organized within tightly regulated institutional frameworks that govern access, terms of exchange, reporting requirements, or public accountability; some examples include stock markets, commodity exchanges, and other financial markets. Whether informal or formal, the frameworks of regulation that encompass the smooth functioning of any market usually mix self-regulating mechanisms created by market participants themselves with those imposed by political or legal authorities. The social, institutional construction of trade and markets is evident in the widely varied price mechanisms – bartering, bidding, haggling, setting posted prices, or negotiating contracts, as well as discounts, rebates, or kickbacks – that are established in various markets, reflecting and shaping very different balances of market power among buyers and sellers.

Markets as Institutions

Anthropologists focus ethnographically on the social structure of markets as institutional systems, the transactional behavior of market participants, and networks among trade partners or among markets (Plattner, 1985). They emphasize how economic activity is embedded in social institutions and relationships which structure solutions to economic problems (sometimes conceptualized as 'transaction costs' (Acheson, 1994)). These costs, which any market or enterprise inevitably faces, are not only direct overhead expenses on specific exchanges. More generally, the economic and social costs of exchange include those of establishing trust and reliability among trade partners, soliciting or extending credit, guaranteeing stable sources of supply, enforcing compliance with agreements, recruiting labor, distributing profits, monitoring employees, obtaining information on market conditions, creating or enforcing property rights, managing risk, and so forth (Geertz, 1978).

Various patterns of social structure that enable markets to form and economic transactions to occur are often conceptualized – by anthropologists influenced by institutional economics and sociology – in terms of 'governance structures,' the institutional structures that organize, constrain, and coordinate economic activities, that sanction some behaviors and provide incentives for others. Different governance structures – different forms of market relationships, different forms of business organization – provide different solutions to the challenges of achieving social and economic integration over the 'transaction costs' that all economic institutions must bear. Governance structures are, therefore, social institutions and systems of norms familiar to anthropologists in many other contexts and subject to similar kinds of social and cultural analyses.

Governance structures range along a theoretical continuum, from 'market governance' to 'governance by hierarchy.' In the former, an economic actor relies on the competitive forces of a spot market to obtain the goods, services, and trustworthiness it requires; in the latter, an economic actor controls goods, services, personnel, and reliability through direct ownership and administrative fiat (as in a vertically integrated industrial corporation). Midway between these extremes is governance by 'relational' or 'obligational' contracting, in which partners in ongoing exchange relationships agree, formally or informally, to do business with one another over time, relying on the strength of personal ties (such as trust) to overcome problems that may arise in the relationship because not all the terms and circumstances of trade are (or can be) specified ahead of time.

Anthropological analyses of markets often focus on the social and cultural patterns sustaining this middle form of governance, such as frameworks of self-regulation, the management of common property, the structural relationships between producers and buyers, the disposition of market power, or the political dynamics of trading communities. Other studies examine the creation of personal ties of trust and reciprocal obligation, and the microlevel transactional behavior among individual traders and other market participants. Some studies place market relationships within a broader cultural milieu of interpersonal interactions; still others examine negotiating, bargaining, or haggling as a transactional game through which traders form what Plattner calls 'equilibrating relationships.' Implicit and explicit decisionmaking models used in daily trade have been collected ethnographically to illustrate how economizing strategies are embedded in culturally or socially

specific contexts. Information costs and transactions costs have been analyzed within what Geertz (1978) calls 'bazaar economies.'

Markets and Urban Life

Throughout history, cities and markets have sustained each other, the former providing location, demand, and social context for the latter; the latter providing sustenance, profit, and cultural verve to the former. In many places, towns and marketplaces grew up together, with marketplaces as centers of economic and social life (and eventually political life as well) and as the institutions through which towns and cities were linked to their hinterlands and to other communities. Markets mediate connections and conflicts among very different segments of an economy or a society: across divisions between rural and urban, peasant and capitalist, premodern and modern, colonized and colonizing, or informal and formal sectors. These mediating roles have been examined in urban markets (in the diffuse sense, as in labor markets) and marketplaces (in the more specific sense, of geographically situated hierarchies of trade (Meillassoux, 1971)). Within commercialized economies, distribution channels and markets that connect large-scale business to small-scale family firms are another example of market linkages across social and economic sectors.

Market hierarchies have themselves been a major topic of study. Central place theory analyzes the spatial distribution of markets within hierarchies of settlements ('central places'), and within anthropology has been applied to peasant marketing systems and to interrelationships among urban markets. Alignments of trading patterns within market systems have been shown to be important indicators of a wide variety of other social, political, administrative, and ritual aspects of local, regional, and national organization. Also known as 'regional analysis,' this approach was developed in anthropology by Skinner's ethnographic and historical research on China (Skinner, 1977), and by extensive studies in Meso-America and elsewhere (Smith, 1976).

The cultural environment of trade and marketplaces is also a central aspect of urban life. In the repertoire of crucial social relationships and roles filled by urbanites, Hannerz (1980) includes 'provisioning relationships,' which necessarily involve people in exchange, within and outside of markets. In a spatial sense, marketplaces can be analyzed as a distinctive kind of urban place with economic as well as many political, social, and ecclesiastical functions, but most anthropologists situate marketplaces not simply in spatial terms but within the wider cultural milieu of a society's values, norms, and texture of relationships (Geertz, 1979).

Markets do not just organize sources of supply; they also satisfy (or create) demand and desire, as stages upon which consumption is rehearsed and displayed. Many studies of consumption take Bourdieu's perspectives on 'taste,' 'distinction,' and 'cultural capital' as points of departure for examining the cultural force of markets in shaping contemporary urban life. Studies of the logic of market capitalism and how it permeates one's experience of shopping and consumption echo Simmel's perspectives on market mentality as the quintessential condition of urban life. So too, did Redfield and Singer's earlier formulations of 'the cultural role of cities,' which placed the marketplace at the heart of the 'heterogenetic city,' a city that links itself to a wider world and, in the process, transforms the city, the rural hinterlands with which the city is interdependent, and society at large.

Markets and Globalization

More recently, sweeping transnational economic, political, and social forces have eroded the separability of societies and perhaps have disestablished the primacy of cities as nodes of exchange, but have accentuated the importance of markets. Since the early 1990s, proponents of globalization as a distinct type of social transformation have emphasized markets (in their deterritorialized sense) as central to this change. Globalization, in this view, is the expansion and ultra- integration of markets on an unprecedented scale, creating markets that incorporate societies, social sectors, and commodities that had formerly resisted or been outside market spheres of exchange. This process presumably has weakened nation-states, and has been facilitated by the increasing speed (or fluidity) of communications, transportation, media, and flows of goods, financial assets, and people, all sustained and accelerated by major technological breakthroughs in electronic media and information processing.

Of course, new patterns of global integration formed around markets are themselves nothing new. Anthropologists and sociologists have examined trade and market hierarchies as they establish linkages throughout what Immanuel Wallerstein conceptualized as the 'world system.' Within this expansion of Western European societies to incorporate most of the globe into their spheres of economic, political, and military hegemony, markets have been critical organizing principles for economic, social, political, and cultural phenomena on regional and national as well as global scales. The political economy of the contemporary world system can be seen through complex networks of 'commodity chains': the links, stages, and hands through which a product passes as it is transformed, fabricated, and distributed between ultimate producers and ultimate consumers (Gereffi and Korzeniewicz, 1994). Such chains connect far-flung components of the 'global factory,' the international division of labor among societies whose specialized niches in the world economy may center on resource extraction, low-cost fabrication, transportation efficiencies, or highly developed consumer markets.

Commodity chains are useful for understanding the widely dispersed industrial production characteristic of contemporary transnational trade as well as the fluidity of the circulation of agricultural and other commodities between producer societies on the global periphery and consumer societies of the global core. Sugar, for example, stands as a commodity at the intersection of imperialism, the colonization of the Caribbean as a region of plantation-slave societies, and Western European industrialization (Mintz, 1985). The contemporary coffee trade in the Western

Hemisphere reflects North American hyperconsumerism and the skillful marketing efforts of mass-market 'boutiques' for 'yuppie coffee,' which form new structural linkages between producer and consumer societies within systems of cultural symbolism and identity based on consumption style (Roseberry, 1996).

Against a backdrop of globalizing markets for commodities, people, assets, and images, Appadurai (1996) proposes that contemporary ebbs and flows of transnational culture be conceptualized as 'ethno- scapes,' 'technoscapes,' 'finanscapes,' 'mediascapes,' and 'ideoscapes.' Very roughly, these refer to the complicated tides and undertows of people(s), of technology, of capital, of media representations, and of political ideologies that concurrently link and divide regions of the globe. These 'scapes' resemble diverse and intersecting markets that exchange items and images across the globe, and across domains, creating value and the possibility of exchange through unexpected juxtaposition and disjuncture. Appadurai's vision of global integration (or disintegration) implies a deterritorialized world in which *place* matters little, but the fluidity of exchange is everything. These loosely coupled domains are organized around particular processes (migration, investment, representation, or consumption), and a varied repertoire of influences may travel quickly, in many directions almost simultaneously, across these domains. The center or disseminator of influence on one 'scape' may be simultaneously the periphery or recipient of influence on another. This decentralized, deterritorialized global culture is a world of many markets (broadly conceived) but few marketplaces, few specific central places of interaction. In contrast, Hannerz (1996) locates these processes (or markets) in world cities, nodes that receive, coordinate, and disseminate cultural content and creativity to locally synthesize global elements into diverse, multiple patterns of regional culture.

The trends that created this 'global cultural supermarket' (to use Stuart Hall's phrase) involve markets more than just metaphorically. The commodification of human bodies in global flows of guest workers, sex workers, and refugees involves markets of hope, desire, and misery. Global industry's ability to shift production from place to place has created markets for 'pollution credits' among different jurisdictions. The development of deep-sea diving equipment has reinvigorated debates over ownership of the seabed, and has vastly extended property rights regimes over global oceans. Electronic media have created commercial forms – online auction sites, for example – that raise familiar questions about trade partnerships, rules of trade, and principles of reliability. Global financial markets can now operate 24 hours a day, further transcending spatial and temporal (and hence political) limitations on their operations. The digitization of information into electronic form has created new forms of property rights (patents and copyrights) based on the value of – and the exchange rights inherent in – retrieval systems rather than underlying information. Common cultural heritage has been converted to 'content,' a commodity with which to fill information delivery systems. Biotechnology has created new crop species, and hence questions about the ownership of both new and existing species and the digitized information on human and other genomes as they are decoded. Increasing exploitation of natural resources raises questions about the common property rights of nations and communities over ecosystems, as well as about the ownership and marketability of indigenous knowledge about local biota, itself a source of valuable data for bioprospecting.

The fundamental issues of anthropological interest in markets and exchange (what is property? who can own it? how can it be exchanged?) are not issues simply of trying to understand small-scale, isolated societies in antiquity and the recent past. How markets are constituted, who has access to them, and how they affect the social order as a whole continue to be current issues, affected by the transformations now taking place on a global scale, creating new integrations of local and transnational market systems centered around new forms of property and new media of exchange. Anthropological analyses of these markets address cultural and social issues as fundamental as those raised by analyses of traditional patterns of exchange in peasant marketing systems. Anthropological interest in markets will continue to focus on emerging practices of capitalism as a global cultural and social system.

Markets: Artistic and Cultural

Victoria D Alexander, University of Surrey, Guildford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article gives a brief overview of the development of markets for the sale of fine arts, the development of nonprofit organizations for the distribution of cultural forms, and the growth of for-profit cultural industries. Issues that affect both nonprofit cultural organizations and the profit-seeking cultural industries are discussed. Key concepts involve the effects on art and culture of uncertainty, the laws of supply and demand, and the responsiveness of markets to buyers' and sellers' desires. Cultural markets are currently in flux due to changes wrought by the Internet.

Introduction

A market is a forum for exchange between buyers and sellers. In the artistic and cultural realms, the term refers to a system for the production and distribution of the arts or culture. Such systems differ from a purely atomistic market in that actors (buyers, sellers, and intermediaries) include both organizations and individuals. All major cultural markets include institutional players in the form of profit-seeking businesses or nonprofit agencies (Caves, 2002).

Many approaches to artistic and cultural markets draw strong distinctions between high and popular culture. High culture, such as opera, theater, symphony, and the visual arts, is often distributed by nonprofit organizations, and is said to be oriented toward the artist. Popular culture, by contrast, is often distributed by profit-making organizations and is said to be oriented toward the consumer (see Gans, 1974). Changes in society and in our understanding of culture have blurred the distinction between fine and popular, and some fine arts are notably distributed through profit-seeking means. The laws of supply and demand apply regardless of whether the organizations involved are profit-seeking. Characteristics of the production system – levels of uncertainty, ambiguity, and risk; market concentration and the level of competition; the ratios of buyers, sellers, and intermediaries – shape not only factors such as the price of an object or performance, but also content of the art itself (Crane, 1992).

History

White and White's (1993[1965]) important work, a sociological study of the transformation of the French art world, shows that the market for fine arts emerged at the end of the nineteenth century. Previous systems in the arts included patronage, guild, and academic systems, which supported the production of art, but it was not until this time that the practice of exchanging of artworks for money in a marketplace became common. By the latter half of the nineteenth century, the French academic system had been successful for more than two centuries. It failed when the number of aspiring artists in Paris vastly outnumbered the rewards (prizes and academic appointments) available through the academy. The surplus artists wanted an outlet for their work and a means to make a living, so they turned to dealers, people who would sell their works directly to the public. In this way, White and White argue that the dealer–critic system emerged to supplant the academic one. Critics were a key component in this new system, as they worked with dealers and artists to create an aesthetic system that justified the new forms of painting. In conveying these ideas to the public, critics helped to create demand for an artist's work.

Proper markets for the popular arts also emerged, more or less, at the end of the nineteenth and the beginning of the twentieth century (Starr, 2004). These cultural markets arose as the cultural industries developed. Initially criticized, most notably by the Frankfurt School (Adorno, 1991), for promoting lowest-common-denominator pabulum, cultural industries grew, along with other industries, in their ability to capture niche markets and to create value from innovation (Lampel et al., 2000; Lopes, 1992).

White and White demonstrate that the system through which French painting was produced influenced the content of the artworks themselves. The academic system rewarded individual paintings exhibited in salons. The dealer–critic system, on the other hand, had different requirements. Dealers needed to sell a continuing stream of paintings, and as a result, had an interest in differentiating their artists' products by referring to each artist's unique style. Paintings were purchased by middle-class buyers, as well as more wealthy patrons, and so were more likely to be hung in houses than in museums. This meant that small, easel paintings were preferred to monumental works and that decorative scenes of landscape and everyday life were preferred to more complicated allegorical or historical works. Each of these requirements, along with a number of others, dovetailed with the new movement in painting, Impressionism. Though clearly there is more to artistic change than just the particular mechanisms that reward artists, White and White demonstrate the influence that these institutional arrangements had on aesthetic possibilities.

In an important article, Peterson and Berger (1975) showed how concentration in the music industry affected the innovation and diversity of hit songs. Indeed, the production of culture approach (Peterson and Anand, 2004) has strongly demonstrated effects of various market arrangements on aesthetic possibilities and the content of art.

In a classic study of market effects on artistic and cultural organizations, the economists Baumol and Bowen (1966) focused on the performing arts. Their much cited finding is that over time the performing arts become increasingly expensive relative to the cost of living, because the number of personnel needed for performances – the musicians in an orchestra, say, or actors in a play – is difficult to reduce. As a result, the performing arts do not see the productivity gains realizable in manufacturing industries. Performing arts, like other service industries, face increasingly expensive payroll bills. Thus, the performing arts always struggle to find external funding, charge higher ticket prices, or suffer cuts.

The studies by Baumol and Bowen (1966), Peterson and Berger (1975), and White and White (1993[1965]) were important in setting the stage for serious study of the distribution mechanisms and economics of the arts. Since their studies were published, there has been a convergence of interest in artistic and cultural markets in a variety of disciplines. Scholarship in this area accelerated through the 1980s (Frey and Pommerehne, 1989; Heilbrun and Gray, 1993), and explicit attention to artistic and cultural markets has received scholarly attention since the turn of the millennium (Caves, 2002; Hesmondhalgh, 2007).

Uncertainty

In an influential article, Hirsch (1972) looked at the distribution of popular arts by profit-seeking organizations in cultural industries. Focusing on popular books and records, he demonstrated that cultural industries are characterized by uncertainty. Record companies and publishers wished to make a profit, but they were not sure which books and albums would succeed. They responded to this situation in a variety of ways, most notably through the strategy of overproduction. They produced many more albums and books than they could possibly sell, with the full knowledge that most would not break even. A small proportion would earn a modest return, and a very few would be phenomenally successful. These last, the blockbusters (or hits), generate enough income to cover the losses on the failures and to make a profit for the company. A second strategy taken by firms was to look at what had been recently successful and to overproduce cultural objects in the same genre or format. In this way, change in cultural industries is often trendy, following fads and fashion.

A key concept in Hirsch's work is the idea of a gatekeeper, a person, or an organization who allows only certain objects into a system. Gatekeepers are important for the content of artwork, as their guesses on what will succeed, their personal tastes, and even their unquestioned cultural assumptions can affect what they accept and reject (Griswold, 1992). Gatekeepers do not directly mold artworks, but in deciding what works to produce or distribute, they determine the range and therefore the content of the artwork that actually reaches the public.

Art Worlds

The work of sociologist Howard Becker is extremely important in cultural sociology. Becker's (1982) key idea is that art is created in rich social networks called 'art worlds.' The characteristics of art worlds create a pattern of constraint and possibility that affects the production and distribution of art, and therefore the artists and their works. Becker's discussion of markets falls under his consideration of distribution systems. He suggested that distribution systems matter, especially to artistic reputation. What is not distributed cannot gain recognition or be remembered. He identifies three key mechanisms by which the arts are supported. The first, self-support, where an artist relies on a day job, a spouse, or an inheritance for monetary needs and produces art 'on the side,' may be the most purely atomistic market in arts distribution, or it may lack any market element. As Becker notes, self-supported art is often not distributed at all, let alone widely. Patronage – whereby a buyer commissions art, either a specific work or a part of the artist's general output – is the second mechanism, and has a clear market component. Patronage sounds genteel, and requires that only one buyer be pleased. It is a form of support that can foster innovation – if the buyer values this – but clearly only within the bounds of the buyer's taste and inclinations.

The third mechanism is public sale, and Becker discusses three types of public sale. Dealers act as intermediaries between artists and buyers where the artwork is a physical object (a painting, sculpture, or installation). Impresarios mediate between artists and audiences in the performing arts (theater, symphony, dance, or experimental performance art). Culture industries are comprised of organizations that link artists who produce works that exist in multiple copies (books, records, movies, film, and television shows) to a large number of consumers.

The 'High Culture' Model

DiMaggio (1982, 1992) shows that, during the late nineteenth and early twentieth century in America, art forms that are considered 'high culture' came to be distributed via nonprofit organizations. As a legal form, nonprofit organizations are constituted 'for the public good,' and because they offer public benefits, they are entitled to tax relief. DiMaggio (1982) shows that, in the late nineteenth century, 'cultural entrepreneurs' founded nonprofit orchestras and art museums in order to advance their interests by embedding their own cultural forms into a situation that conferred both a favorable tax regime and prestige. In the early twentieth century, opera and ballet companies and certain theaters incorporated as nonprofit organizations (DiMaggio, 1992). Nonprofit performing arts organizations offer an important outlet, a market we could say, for the sale of live performance. While museums act as repositories of the visual arts, rather than venues for exchange of artworks, they also provide an opportunity to experience art. Importantly, nonprofit organizations allow champions of each art form to create a boundary between a high-status version of the art form and its more popular and commercial relatives. In contrast, a more pure marketplace works against distinctions in culture, as it "drives entrepreneurs to elide aesthetic distinctions in order to create larger audiences and discourages canon formation by providing incentives for presenters to differentiate their products" (DiMaggio, 1992: 43–44).

The Marketization of Art Museums

Museums play a number of key roles in the visual art world; notably, they are the venue in which most ordinary viewers confront original art. American art museums gain income from grants for special exhibitions, especially from corporations and government agencies, alongside traditional patronage. In addition, American museums rely on earned income through general admission charges, gate receipts for special shows, and the sale of merchandise, books, and souvenirs. This funding situation has important implications for the art that is displayed in museums and for museum audiences (Alexander, 1996). Interestingly, art museums across the globe are facing similar pressures, as they are increasingly 'privatized' (Boorsma et al., 1999), that is, moved away from direct state support to a 'mixed economy' of fund-raising from private sources and earned income, most of which is linked, directly or indirectly, to the marketplace. The term marketization is used to indicate that a type of culture once produced and distributed in nonmarket settings has moved into market (or market-approximating) ones. Broadly, the term also indicates that a neoliberal way of thinking has pervaded settings that used to be 'pure.'

Marketized cultural organizations, such as museums, must pay attention to audiences. Not only do audiences bring in money directly in terms of entrance fees and sales, they also influence project funding. Both corporations and government agencies are concerned with the size of the audience their funded projects might attract (Alexander, 1996). This has led museums to operate, in essence, as public sales organizations, in that their exhibitions must appeal to the people who will 'buy' them. Museum curators remain committed to scholarly exhibitions and are less interested in popular ones, but the latter are easier to fund and the public likes them, so curators try hard to mount shows that are both scholarly and popular.

An interesting change has taken place in art museums over the last few decades: a shift in the basic assumptions of those in charge of museums, from a more scholarly approach to a more managerial one. Collecting, conservation, and connoisseurship remain mainstays of art museums. But a focus on business-world concerns – marketing a product, value for money, and the like – has pervaded museums. Some, particularly those with a business or economics background, see this in a positive light, as evidence that museums have entered the modern world and will finally be managed in a sensible way. Others, especially those vested in the older values system, see this as a corruption of museums, debasing the art and bringing crass considerations like the bottom line to a sacred arena where monetary concerns should be left aside.

Visual Art Markets

In the visual arts, separate markets exist for consecrated works (old masters and more recent artists with strong reputations), the contemporary avant-garde, contemporary decorative/figurative art, and art made by anonymous masters from developing countries (tribal art). An international market exists for each of these types of art, except the decorative arts, which is the most varied market and is sold by dealers in national, regional, or local markets, (Plattner, 1996; O'Neil, 2008) or even in such outlets as craft fairs and street stalls (Paulsen and Staggs, 2005).

Unlike most artistic markets, the market for consecrated works (those by 'old masters') is characterized by undersupply – there are fewer works of art than buyers wanting them. As a result, such works are often sold at auction where competing buyers can bid up prices to extraordinary heights (Thornton, 2008). But prices can differ substantially from the estimates of the auction houses, because social expectations and the dynamics of the auction floor, not just the laws of supply and demand, affect bids (Smith, 1990). These factors add a degree of uncertainty to the secondary (auction) market (Thompson, 2008).

Consecrated works are almost always pieces that are being 'resold' by an owner, which is why the market is called the 'secondary' art market. Artists in the secondary market have already been market tested during their previous sales history. Uncertainty is higher in the avant-garde setting, in the 'primary' market where art is sold via dealerships, both for artists and dealers, as new artist are, obviously, untested in the marketplace. The prestigious avant-garde markets are concentrated in a few world-class cities, notably New York, London, and Paris. A problem for dealers – the same faced by cultural industry executives – is to choose artists who will succeed. There are huge numbers of artists hoping to be discovered and shown, and it is difficult to predict those whom posterity will remember. The solution is to promote a relatively large number of artists as compared with the numbers who will succeed (a strategy of 'overproducing'). However, relatively few artists break through even to the level of success indicated by representation by an important dealer. As with other art markets, the avant-garde market is characterized by a 'winner-take-all' reward system where a few superstars receive the lion's share of the returns (see Rosen, 1981). This means a few contemporary artists will be phenomenally successful and become rich, a modest number will just scrape a living and most will have to supplement their incomes elsewhere.

Dealers may also promote artists who work in styles similar to those that have recently been successful. Unlike cultural industry executives, they do not profess this mimicking strategy, as it goes against central tenets of avant-garde art, namely, the sanctity of artistic choice, free from the interference of dealers. Velthuis (2005) points out that art dealers do not openly discuss prices, as to do so would undermine the pretense that art is completely separated from the marketplace and commercial concerns. Art dealers, nevertheless, are clearly commercial and profit-seeking.

The oversupply of artists leads to suppressed prices for art in general, and art dealers need to set prices in the absence of objective criteria for doing so. Clearly dealers have an incentive to limit market entry and to keep prices at a certain level. Their techniques include discouraging their artists from underselling the dealer, convincing potential buyers that gallery prices for emerging artists are a fair expression of their future potential, and excluding buyers who might 'flip' a work at auction and thereby undermine the dealer's pricing system. Velthuis (2005) discusses the many ways that the laws of supply and demand are subverted in the international visual arts market.

The largest, headline-grabbing sums in the visual arts belong to the old master and avant-garde markets. Figurative

and decorative arts are devalued relative to avant-garde art. The aesthetic system, prestigious dealers, and relative centralization that provide entry barriers in the avant-garde world do not exist in the decentralized figurative art market. As a result, prices are lower in this market. However, as Martorella (1990) demonstrates, corporations wishing to buy prestigious art also prefer noncontroversial, figurative art. Their presence in the art market has helped legitimize some forms of figurative art. American corporations' interest in collecting regional artists has also reinforced the decentralization in the figurative art market.

The market for tribal art (previously referred to as 'primitive' art) is also smaller and attracts lower purchase prices. The operation of this market raises questions about the exploitation of artists from developing countries by dealers and patrons in the first world (Price, 1989). Today, third-world masters are usually named and their work given the title of art, rather than cast anonymously as an expression of tribal visions. Issues such as cultural imperialism are less salient in markets for avant-garde and figurative art (though certainly not nonexistent), but play a key role in markets for other types of culture, notably film and television.

Moulin (1987) argues that the economic value of an artwork and its artistic value are inseparable and synonymous. An economist would argue, then, that the market was efficient in that it properly prices works based on aesthetic value. But it is also possible to argue that the economic value, rather than reflecting aesthetic value, creates it by attracting the attention of art critics and the cultural cognoscenti and setting in motion the theorizing necessary to underpin an artist's style.

As Menger (1999) demonstrates for a wide variety of artists in different cultural industries, more talent exists than do outlets for it. As a result, artistic careers are risky for artists. Most support themselves economically with a second job. The situation, as with other contingent labor markets (where employers hire workers only when work is available) provides a great deal of flexibility to dealers, and the other cultural organizations that rely on contingent labor, but this arrangement shifts costs from the organization to the individual.

Can Culture Survive the Marketplace?

An old but still important question is how market systems, as opposed to other forms of support, affect culture. Given the pervasive oversupply of artworks and artists, it follows that in artistic and cultural markets sellers must attract buyers. Art that no one wants simply cannot be supported by the market. Moreover, markets imply profits. In this case, not only must buyers exist, but also there must be enough of them for sales to cover production and overhead costs and to leave a surplus. The larger the audience needed, the more popular the product must be, and as a corollary, the lower the common denominator. Indeed, as cultural critics for more than a century have lamented the degraded nature of mass culture, contemporary critics worry about the declining state of art.

Not-for-profit enterprises may seem a good alternative to commercial industries, but the need to attract an audience is not limited to for-profit enterprises. Not-for-profit organizations must also reach sufficient audiences while facing an inexorable upward spiral of costs, as Baumol and Bowen showed nearly 50 years ago. These pressures, along with the privatization of arts funding, lead nonprofit enterprises to approximate profit-seeking systems in all but their requirement to return dividends to shareholders.

DiMaggio (1986) argues that large, established arts institutions can survive the marketplace. With proven repertoires of established works well accepted by the public, they can generate significant earned income. They may subsidize an innovative program with known crowd-pleasers, such as *The Nutcracker*, *The Messiah*, or Monet's *Water Lilies*. In addition to their ability to attract the 'middlebrow,' they have the organizational size and expertise to raise funds for such projects.

Since innovative, experimental works may be least likely to survive the marketplace, some have argued that there is a societal interest in subsidizing a supply of unpopular (or rather, not yet popular) artists through government funding. While generous state sponsorship can have a positive effect on innovation and diversity in the arts, not to mention making the lives of artists easier, it is worth noting that results depend on national politics (Alexander and Rueschemeyer, 2005). For instance, art in Soviet societies was strongly supported by the state – and highly constrained, and political controversies in the US served to narrow the type of art and artists sponsored by the federal government.

New Technologies

A key point of uncertainty for the future of artistic and cultural markets is the influence of new technologies, especially the Internet. The music industry, for instance, has been transformed by the digital age, and new business models are in the offing (Kusek and Leonhard, 2005). Gatekeepers within cultural industry systems have been powerful intermediaries – and barriers – between artists and the public. Today, artists reach out to the public via the Internet. There have been notable successes via this 'direct' route, but gatekeepers, of one sort or another, are likely to remain important, if only by providing help to consumers (buyers) in sifting through nearly endless possibilities for arts products and experiences.

Anderson (2006) describes the new cultural economy in which mass markets aimed toward 'hits' is joined, or even supplanted, by the 'long tail' in which cultural products attracting very small audiences can be marketed. In other words, technology drives niche marketing to the extreme, allowing profitable sales of even a few copies of a cultural product. While there is not much money in each sale in the long tail, the number of sales can add up to be enormously profitable. Amazon takes a long-tail approach, and makes more than half of its book sale profits from titles not sold in most mass-market bookstores (Anderson, 2006). Apple's iTunes and streaming services, such as Spotify and Netflix, also aim to make profits in the long tail.

Other cultural institutions are increasingly making use of digital technology. Most museums provide Web pages with digitized images from their collection, and Google's Cultural Institute and its associated Google Art Project allow viewers to take digital tours, via Street View technology, of galleries

in the world's great museums. Performing arts organizations offer 'trailers' of upcoming work on their home pages. The Metropolitan Opera simulcasts high-definition recordings of live performances to cinemas across the globe. While it is unclear what directions these changes will take nonprofit organizations and cultural industries, the implications for arts markets, not to mention artists, artworks, and audiences, are potentially enormous.

Summary

The scope for research in the area of artistic and cultural markets is vast. Even leaving aside artistic labor markets, the topic encompasses such areas as the international market for visual arts; auctions of contemporary works of art and of works by old masters; the funding dynamics of such arts organizations as museums or symphonies; the Hollywood film production and distribution network; film production elsewhere in the world, such as India's Bollywood; book publishing; television broadcast; the international flow of programing; music; radio; digital games; and much more from across the fine and popular arts. Tourism, visits to both heritage sites and entertainment centers like Disneyland, could be considered part of the global cultural market. Further, many consumer products, from soft drinks to jeans, are items of popular culture, and it would be easy to include an array of consumer markets as part of the cultural marketplace. Indeed, some theorists of consumerism would argue that all forms of contemporary purchasing belong to the cultural realm.

This article adopted a more limited view of the huge array of artistic and cultural markets, focusing on markets for the distribution of fine and popular arts. Although it could only scratch the surface of the subject, it highlighted the key characteristics of the means by which the fine and popular arts are distributed to consumers, either through cultural industries or nonprofit enterprise. Some more specific examples from the visual arts were provided. Most of the effects of the market on visual arts have complements in other artistic and cultural markets, though specific details will naturally vary from one art form to another. The main line of agreement among scholars is that, in contemporary Western societies, the arts are profoundly shaped by their market characteristics. Market and marketized settings in art and culture are more responsive to the desires of the buyers than those of the sellers; consequently, artists who do not gear their work toward audiences do not sell well, and cultural organizations that do not offer popular fare, or that are unable to tap into specialized, niche markets, also pay the price.

Markov Chain Monte Carlo Methods

Abstract

Markov chain Monte Carlo (MCMC) methods use computer simulation of Markov chains in the parameter space. The Markov chains are defined in such a way that the posterior distribution in the given statistical inference problem is the asymptotic distribution. This allows use of ergodic averages to approximate the desired posterior expectations. Several standard approaches to define such Markov chains exist, including Gibbs sampling, Metropolis–Hastings, and reversible jump. Using these algorithms it is possible to implement posterior simulation in essentially any problem which allows pointwise evaluation of the prior distribution and likelihood function.

Introduction

In Bayesian statistics the posterior distribution $p(\psi|y)$ contains all relevant information on the unknown parameters ψ given the observed data y. All statistical inference can be deduced from the posterior distribution by reporting appropriate summaries. This typically takes the form of evaluating integrals

$$J = \int f(\psi)p(\psi|y)d\psi \qquad [1]$$

of some function $f(\psi)$ with respect to the posterior distribution. For example, point estimates for unknown parameters are given by the posterior means, that is, $f(\psi) = \psi$; prediction for future data $\tilde{y}$ is based on the posterior predictive distribution $p(\tilde{y}|y) = \int p(\tilde{y}|\psi, y)p(\psi|y)d\psi$, that is, $f(\psi) = p(\tilde{y}|\psi, y)$, etc. The problem is that these integrals are usually impossible to evaluate analytically. And when the parameter is multidimensional, even numerical methods may fail.

Since the 1980s a barrage of literature has appeared concerned with the evaluation of such integrals by methods collectively known as Markov chain Monte Carlo (MCMC) simulation. The underlying rationale of MCMC is to set up a Markov chain in ψ with ergodic distribution $p(\psi|y)$. Starting with some initial state $\psi^{(0)}$ we simulate M transitions under this Markov chain and record the simulated states $\psi^{(j)}$, $j = 1, \ldots, M$. The ergodic sample average

$$\widehat{J} = \frac{1}{M}\sum_{j=1}^{M} f\left(\psi^{(j)}\right) \qquad [2]$$

converges to the desired integral J (subject to some technical conditions), that is, $\hat{J}$ provides an approximate evaluation. The art of MCMC is to set up a suitable Markov chain with the desired posterior as stationary distribution and to judge when to stop simulation, that is, to diagnose when the chain has practically converged.

In many standard problems it turns out to be surprisingly easy to define a Markov chain with the desired stationary distribution. We will review the most important approaches in this article (for general principle of Monte Carlo simulation, including independent Monte Carlo simulation, see Monte Carlo Methods and Bayesian Computation: Overview).

The Gibbs Sampler

Consider a variance components model $y_{ij} = \theta_i + e_{ij}$, $i = 1, \ldots, K$ and $j = 1, \ldots, J$, for data y_{ij} from K groups with J observations in each group. Assume independent normal errors $e_{ij} \sim N(0, \sigma_\theta^2)$ and a normal random effects model $\theta_i \sim N(\mu, \sigma_\theta^2)$ (Gelfand et al.1990). We assume that $\theta = (\theta_1, \ldots, \theta_k)$, (μ, σ_θ^2) and σ_e^2 are *a priori* independent with $p(\sigma_\theta^2) = IG(a_1, b_1), p(\mu|\sigma_\theta^2) = N(\mu_0, \sigma_\theta^2)$, and $p(\sigma_e^2) = IG(a_2, b_2)$. Here we use $N(m, s^2)$ to indicate a normal distribution with moments m, s, and $IG(a, b)$ to indicate an inverse gamma distribution with parameters a and b. Let $y = (y_{ij}, i = 1, \ldots, K, j = 1, \ldots, J)$ denote the data vector. It can be shown that the conditional posterior distributions $p(\sigma_\theta^2|y, \mu, \theta, \sigma_e^2)$ and $p(\sigma_e^2|y, \mu, \theta, \sigma_\theta^2)$ are inverse gamma distributions, and $p(\mu|y, \theta, \sigma_\theta^2, \sigma_e^2)$, and $p(\theta|y, \mu, \theta, \sigma_\theta^2, \sigma_e^2)$ are normal distributions.

To estimate posterior moments of the type (1) we define a Markov chain in $\psi = (\mu, \theta, \sigma_e^2, \sigma_\theta^2)$. Denote with $\psi^{(t)} = (\mu^{(t)}, \theta^{(t)}, \sigma_e^{2(t)}, \sigma_\theta^{2(t)})$ the state vector of the Markov chain after t transitions. Given the nature of a Markov chain, all we need to define is the transition probability, that is, given a current value for $\psi^{(t)}$, we need to generate a new value $\psi^{(t+1)}$. We do so by sampling from the complete conditional posterior distributions for $\mu, \sigma_e^2, \sigma_\theta^2$ and θ

a. $\mu^{(t+1)} \sim p(\mu|y, \theta^{(t)}, \sigma_e^{2(t)}, \sigma_\theta^{2(t)})$
b. $\theta^{(t+1)} \sim p(\theta|y, \mu^{(t+1)}, \sigma_e^{2(t)}, \sigma_\theta^{2(t)})$
c. $\sigma_e^{2(t+1)} \sim p(\sigma_e^2|y, \mu^{(t+1)}, \sigma_e^{(t+1)}, \sigma_\theta^{2(t)})$
d. $\sigma_\theta^{2(t+1)} \sim p(\sigma_\theta^2|y, \mu^{(t+1)}, \theta^{(t+1)}, \sigma_e^{2(t+1)})$

Steps (a) through (d) define a Markov chain $\psi^{(t)}$ which converges to $p(\mu, \theta, \sigma_e^2, \sigma_\theta^2|y)$, as desired. Ergodic averages of the type $\widehat{J} = 1/M \sum f(\psi^{(t)})$ provide numerical evaluations of any desired posterior integral J.

The described Markov chain Monte Carlo simulation is a special case of a Gibbs sampler. In general, let $\psi = (\psi_1, \ldots, \psi_p)$ denote the parameter vector. The Gibbs sampler proceeds by iteratively, for $j = 1, \ldots, p$, generating from the conditional posterior distributions

Figure 1 Gibbs sampler. The grey shades show a bivariate posterior distribution $p(\psi_1, \psi_2|y)$. The connected points show the parameter values $\psi^{(t)}$ generated in $M = 40$ transitions of the MCMC simulation. The transition probabilities in the Gibbs sampler are the full conditional posterior distributions (3), leading to the piecewise horizontal and vertical trajectories seen in the figure. Each horizontal line segment corresponds to generating a new value $\psi_1^{(t+1)} \sim p(\psi_1|y, \psi_2^{(t)})$. Each vertical line segment corresponds to generating $\psi_2^{(t+1)} \sim p(\psi_2|y, \psi_1^{(t+1)})$.

Figure 2 Metropolis sampler. The grey shades show a posterior distribution $p(\psi|y)$. The connected solid points show the parameter values $\psi^{(t)}$ generated in $M = 40$ transitions of a Metropolis chain with bivariate normal proposals $\tilde{\psi} \sim N(\psi, 0.75I)$, where I denotes the 2×2 unit matrix. The empty circles show generated proposals $\tilde{\psi}$ which were rejected using the acceptance probabilities (4). Compare with Figure 1 which shows a Gibbs sampler with an equal number of transitions.

$$\psi_j^{(t+1)} \sim p\left(\psi_j|\psi_1^{(t+1)}, \ldots, \psi_{j-1}^{(t+1)}, \psi_{j+1}^{(t)}, \ldots, \psi_p^{(t)}, y\right) \qquad [3]$$

If practicable it is advisable to generate from higher dimensional conditionals.

Figure 1 illustrates the Gibbs sampling algorithm. The figure shows simulated parameter values for a hypothetical bivariate posterior distribution $p(\psi_1, \psi_2|y)$.

The seminal paper by Gelfand and Smith (1990) and the companion paper by Gelfand et al. (1990) popularized the Gibbs sampler for posterior simulation in a wide class of important problems. Many earlier papers used essentially the same method in specific problems. For example, a special case of the Gibbs sampler occurs in problems with missing data. In many problems, the actually observed data y can be augmented by missing data z in such a way that simulation from $p(\psi|y, z)$ and $p(z|\psi, y)$ can be implemented in computationally efficient ways, even when simulation from the original posterior distribution $p(\psi|y)$ is difficult. Tanner and Wing (1987) propose what is essentially a Gibbs sampler for the augmented posterior distribution $p(\psi, z|y)$. Geman and Geman (1984) proposed the Gibbs sampler for posterior simulation in a spatial model with a Markov random field prior.

The Metropolis–Hastings Algorithm

The Gibbs sampler owes some of its success and popularity to the fact that in many statistical models the complete conditional posterior distributions $p(\psi_j|\psi_i, i \neq j, y)$ take the form of some well-known distributions, allowing efficient random variate generation. But there remain many important applications where this is not the case, requiring alternative MCMC schemes. Possibly the most generic such scheme is the Metropolis scheme (Metropolis et al. 1953). Consider generating from a posterior distribution $p(\psi|y)$. Denote with ψ the current state of the Markov chain. One transition is defined by the following steps:

a. Generate a proposal $\tilde{\psi}$ from some proposal generating distribution $q(\tilde{\psi}|\psi)$. The choice of the proposal distribution $q(\cdot)$ is discussed below.
b. Compute

$$a(\psi, \tilde{\psi}) = \min\left\{1, \frac{p(\tilde{\psi}|y)}{p(\psi|y)} \cdot \frac{q(\psi|\tilde{\psi})}{q(\tilde{\psi}|\psi)}\right\} \qquad [4]$$

c. With probability a replace ψ with the proposal $\tilde{\psi}$. Otherwise, leave ψ unchanged.

Figure 2 illustrates the algorithm. The figure shows the proposals $\tilde{\psi}$ and the (accepted) states $\psi^{(t)}$ for the first 40 iterations of a Metropolis chain simulation for a hyptothetical bivariate posterior distribution. The choice of the proposal distribution $q(\tilde{\psi}|\psi)$ is essentially arbitrary, subject only to some technical constraints. Using a symmetric proposal distribution with $q(\tilde{\psi}|\psi) = q(\psi|\tilde{\psi})$, for example a normal centered at ψ, has the practical advantage that the ratio of proposal distributions $q(\psi|\tilde{\psi})/q(\tilde{\psi}|\psi)$ cancels out of the expression for $a(\cdot)$. Often *Metropolis chain* is used to refer to this special case only. Another practically interesting variation is the use of an independent probing distribution $q(\tilde{\psi})$, that is, the proposal is independent of the current state. Tierney (1994) refers to such algorithms as *independence chains*. Hastings (1970) proposes a larger class of similar algorithms based on a more general expression for the acceptance probability. Chib and Greenberg (1995) give a tutorial introduction to the Metropolis–Hastings algorithm.

Convergence

The use of integral estimate (2) requires the verification of two conditions related to convergence.

First, the chain has to theoretically, that is, for $M \to \infty$, converge to the desired posterior distribution. Second, even if convergence for $M \to \infty$ is established, we need a convergence diagnostic to decide when we can terminate simulations in a practical implementation.

Tierney (1994, Theorem 1) shows convergence (in total variation norm) under three conditions: irreducibility, aperiodicity, and invariance.

The Markov chains which are used in MCMC schemes generally use a continuous state space, that is, $\psi^{(t)}$ is a real valued vector. For such continuous state spaces the notion of irreducibility is formally defined as π-irreducibility, with respect to some measure π on the state space. For the purpose of the present discussion we only consider $\pi(\psi) = p(\psi|y)$, that is, π denotes the desired stationary distribution. A Markov chain is π-irreducible if for any state ψ and any set B of states with $\pi(B) > 0$ there exists an integer $n \geq 1$ such that in n iterations the chain can with positive probability make a transition from ψ to some state in B.

Invariance refers to the property that if we start with a state vector generated from the desired posterior distribution, that is, $\psi^{(t)} \sim \pi$, then a further transition in the Markov chain leaves the marginal sampling distribution of ψ unchanged, that is, $\psi^{(t+1)} \sim \pi$.

The Gibbs sampler and the Metropolis–Hastings scheme define Markov chains which by construction are invariant with respect to the desired posterior distribution. Irreducibility and aperiodicity need to be verified, but are usually not a problem. However, sometimes MCMC implementations suffer from practical violations of irreducibility. There might be some subsets of the parameter space which are such that once the Markov chain simulation enters this set it is very unlikely to leave this subset again within any reasonable number of iterations. Such situations occur, for example, in independence chains if the proposal distribution $q(\tilde{\psi})$ has thinner tails than the desired posterior $\pi(\psi)$. The acceptance probabilities, Eqn. [4], include the ratios $\pi(\psi)/q(\psi)$. Assume the chain has generated a parameter value ψ far out in the tail, with very large ratio $\pi(\psi)/q(\psi)$. The chain will then reject any proposed move until a new proposal $\tilde{\psi}$ equally far out in the tail is generated.

Practically more important than establishing theoretical convergence is to recognize practical convergence, that is, to judge when sufficiently many transitions M have been simulated to obtain ergodic averages $\hat{J}$ close to the desired posterior expectations J. The simplest procedure is to plot the trajectories $\psi^{(t)}$ against iteration number t and judge convergence if an informal visual inspection of the plot does not reveal obvious trends. **Figure 3** shows a typical trajectory. Several more formal convergence diagnostics have been proposed in the recent literature. Gelman and Rubin (1992) propose to consider several independent parallel runs of the MCMC simulation. Convergence is diagnosed if the differences of $\hat{J}$ across the parallel runs are within a reasonable range. Gelman and Rubin (1992) formalize this with an ANOVA type statistic. Geweke (1992) proposes to compare an ergodic average based on early simulations (say the first 10 percent of the iterations) with an ergodic average based on later iterations (say the last 50 percent). Under convergence the two ergodic averages should be approximately equal. Using an approximate sample standard deviation based on spectral density estimates allows a formal test.

Figure 3 Convergence. The figure plots the first 2000 steps for the Gibbs sampler shown in Figure 1. The thin black curve plots $\psi_1^{(t)}$ against iteration t. The thick grey curve plots $\widehat{J}_t = 1/t\sum_{j=1}^{t}\psi_1^{(t)}$. After about 500 iterations the estimated posterior mean has practically converged. See the text for a discussion of more formal convergence diagnostics.

These and other convergence diagnostics are discussed in Best et al. (1995) and implemented in the public domain software BOA described there.

Limitations and Further Reading

The Gibbs sampler and the Metropolis–Hastings chain implicitely require a fixed dimension parameter space, that is, the dimension of ψ must not change across different values. This excludes, for example, a regression model with an unknown number of co-variates. In other words, the Gibbs sampler or the Metropolis–Hastings algorithm can not be used for model selection.

Several recent monographs provide more complete reviews of MCMC methods. Tanner (1996) provides an introduction including related schemes such as importance sampling. Assuming basic familiarity with the algorithms, Gilks et al. (1996) discuss Markov chain Monte Carlo simulation in the context of important statistical models. Gamerman (1997) and Robert and Casella (1999) review alternative algorithms and related theory.

Markov Decision Processes

Michael L Littman, Brown University, Providence, RI, USA

Abstract

Markov decision processes (MDPs), an established framework for specifying task environments for decision-making agents, are valuable in the behavioral sciences as a formal description of sequential problems faced by animals and people. This article provides a mathematical definition of MDPs, an example application, an introduction to algorithms for finding optimal policies in MDPs, and a list of useful extensions to the basic model.

Markov decision processes (MDPs) model decision making in discrete, stochastic, sequential environments (*see* Decision and Choice: Sequential Decision Making). The essence of the model is that a decision maker, or agent (*see* Autonomous Agents), inhabits an environment, which changes state randomly in response to action choices made by the decision maker. The state of the environment affects the immediate reward obtained by the agent, as well as the probabilities of future state transitions. The agent's objective is to select actions to maximize a long-term measure of total reward. Efficient algorithms for MDPs based on dynamic programing and linear programing, and more recently on compact representations, enable large planning problems from artificial intelligence, operations research, economics, robotics, and the behavioral sciences to be modeled and solved.

This article describes MDPs, an example application, algorithms for finding optimal policies in MDPs, and useful extensions to the basic model.

MDPs are attractive models of decision making and planning. Because of their more general reward and state-transition structure, MDPs extend standard planning models from artificial intelligence. Interesting environments can be expressed as MDPs. Relatively efficient algorithms exist for computing optimal decision strategies. Using current computer technology, these algorithms scale to MDPs with on the order of multiple millions of states.

Animal-Behavior Example

For a concrete example of an MDP model, consider this fictitious animal-behavior example. A flock of sheep grazes in a meadow. At any given moment, the meadow can have abundant food (s_1), adequate food (s_2), scarce food (s_3), or no food (s_4). Each day, the flock can decide to graze (a_1), search locally for another meadow (a_2), or search more globally for another meadow (a_3). The matrices in Tables 1 and 2 define the MDP. Search action a_2 has the advantage of being relatively cheap, but the disadvantage of not changing the state very much.

Roughly speaking, the sheep should graze when there is adequate food, and otherwise search for a better meadow. But when should they search and what search strategy should they use? The next sections give a formal definition of MDPs and describe how to solve them, providing a precise answer to this question.

Definitions

An MDP is a tuple $M = (S, A, T, R, \beta)$, where

- S is a finite set of states of the environment;
- A is a finite set of actions;
- T: $S \times A \rightarrow \Pi(S)$ is the state-transition function, giving for each state and agent action a probability distribution over states ($T(s, a, s')$ is the probability of ending in state s', given that the agent starts in state s and takes action a);
- $R : S \times A \rightarrow \mathscr{R}$ is the reward function, giving the expected immediate reward gained by the agent for taking each action in each state
  ($R(s, a)$ is the expected reward for taking action a in state s); and
- $0 < \beta < 1$ is a discount factor).

A policy is a description of the behavior of an agent. Because of their simple structure, this article considers only stationary policies, such as π:$S \rightarrow A$. These policies specify, for each state, an action to be taken should the agent find itself in that state.

The total expected discounted reward for a policy π from some initial state is a measure of its long-run success. It is defined as the expected value of the discounted sum of immediate rewards. To be more concrete, let $V^{\pi}(s)$ be the total expected discounted reward for starting in state s and executing policy π

$$V^{\pi}(s) = R(s, \pi(s)) + \beta \sum_{s' \in S} T(s, \pi(s), s') V^{\pi}(s'). \qquad [1]$$

The value function for policy π is the unique solution of this set of simultaneous linear equations, one for each state s. The

Table 1 Reward function and state transition function for the graze action in the fictitious sheep grazing example

s_3	0.1	0.4	0.3	0.2
s_4	0.1	0.4	0.3	0.2

system of linear equations can be solved using any of a number of standard techniques from linear algebra.

Equation [1] derives a value function from a policy. Reversing this, the greedy policy with respect to value function V, π_v, is defined as:

$$\pi_v(s) = \underset{\alpha}{\operatorname{argmax}}\left[R(s,a) + \beta \sum_{s' \in S} T(s,a,s')V(s')\right]. \qquad [2]$$

This policy is obtained by taking the action in each state with the best one-step look-ahead value according to V.

Given an initial state s, the goal is to execute the policy π that maximizes $V^{\pi}(s)$. Howard (1960) showed that a policy π^* exists that is simultaneously optimal for every starting state. The value function for this policy, written V^*, is defined by the set of equations:

$$V^*(s) = \max_{\alpha}\left[R(s,a) + \beta \sum_{s' \in S} T(s,a,s')V^*(s')\right]. \qquad [3]$$

Any greedy policy with respect to this value function is optimal. Thus, the goal of many MDP solution algorithms is finding V^* or a good approximation.

Algorithms for Solving Markov Decision Processes

Solving an MDP means finding the policy π^* that maximizes the total expected discounted reward. Although many approaches have been studied, the simplest and most general is value iteration.

Value iteration treats the equality in eqn [3] as an assignment. It starts off with an arbitrary approximation to V^*, say a value function V that assigns 0 to all states. Over successive iterations, this approximation is improved by using the previous value of V combined with one-step look-ahead to get a more refined estimate. The algorithm terminates when the maximum difference between two successive value functions is less than some predetermined values ($\varepsilon > 0$), at which time the greedy policy with respect to V is returned. The algorithm is guaranteed to terminate, and, if ε is set small enough, the returned policy will be optimal.

Although easy to implement, value iteration can be very slow to converge in some MDPs. For additional computational cost per iteration, policy iteration, due to Howard (1960), results in considerably more rapid covergence in practice. Like value iteration, policy iteration computes a sequence of value functions, V. In policy iteration, V is the value function for the greedy policy with respect to the value function V' from the previous iteration: $V = V^{\pi}_{v'}$. This assignment can be done by applying eqn [2] and then solving eqn [1].

Table 3 Sequence of value functions generated by value iteration in the fictitious sheep grazing example

Iteration	s_1	s_2	s_3	s_4
0	0.000	0.000	0.000	0.000
1	5.000	5.000	2.000	0.000
2	9.230	7.520	2.720	0.000

4	14.234	9.200	3.200	0.073
⋮				
86	19.480	12.502	6.502	3.670

Policy iteration finds the optimal value function and policy after a finite number of iterations. There are a finite number of policies, and each iteration with a nonoptimal policy finds a policy that is a strict improvement over the previous one.

Returning to the animal-behavior example given earlier, value iteration produces the sequence of value function given in Table 3. The table shows the result of the first four iterations of the algorithm and the result of the 86th iteration. After 86 iterations, the value function has converged to within machine precision. From the final value function, the optimal policy is to graze (a_1) in states s_1 and s_2, local search (a_2) in state s_3, and global search (a_3) in state s_4. Value iteration finds this policy after only four iterations, but convergence to the optimal value function takes considerably longer: for accuracy out to six digits past the decimal point, 170 iterations are required. In contrast, policy iteration steps through only one suboptimal value function (for the policy that always chooses a_1) before obtaining the optimal policy and value function and terminating.

As the discount factor β gets close to one, value iteration can require exponentially many iterations to converge. It is possible, although not proven, that policy iteration can also take an exponential number of iterations. The only approach to solving MDPs that has been shown to terminate after a polynomial amount of computation is linear programing (*see* Algorithmic Complexity). Littman et al. (1995) survey computational complexity issues in MDPs.

Related Models and Extensions

Although the type of MDP described in this article is very general and has been extensively studied, other closely related models are also quite useful.

- *Markov games*. In this model, state transitions and rewards are controlled by multiple agents instead of a single agent. Agents select actions to maximize their personal total expected discounted reward. The zero-sum version of this model (*see* Game Theory), first introduced by Shapley (1953), can be solved via variations of value iteration and policy iteration.

- *Partially observable MDPs*. This model is a hybrid of MDPs with hidden Markov models in which the environment's state is only visible via stochastically generated, and possibly ambiguous, 'observations.' Smallwood and Sondik (1973) provide one of the first algorithmic treatments of this model. Both value iteration and policy-iteration algorithms have been studied. A tutorial for behavioral scientists can be found in Littman (2009).
- *Continuous states, actions, and time*. Robotics problems, for example, feature continuous state spaces (e.g., arm angle) and action spaces (e.g., joint acceleration) and must run in real time (*see* Dynamic Decision Making). Puterman (1994) surveys some relevant results.
- *Other objective functions*. The problems of maximizing average reward per step, total expected reward (undiscounted), and worst-case reward all share important features with the total expected discounted reward model described here, although each introduces its own complications.
- *Propositional representations*. Many environments can be best described using states or actions in attribute-value form (e.g., HEALTH = good, AGE = young, SEASON = winter). Boutilier et al. (1999) survey propositional representations of MDPs and attempt to take advantage of these representations to speed the solution process.
- *Value-function approximation*. Another direction is the use of compact parameterized function approximators such as neural networks to store value functions. Bertsekas and Tsitsiklis (1996) dubbed this approach 'neuro-dynamic programing,' and it has been successfully applied to some very difficult sequential decision problems such as helicopter control and move selection in board games.
- *Reinforcement learning*. The MDP model has been embraced by reinforcement-learning researchers as a model of environments faced by agents learning from delayed feedback (Sutton and Barto, 1998). Behavioral and neuroscience applications of this idea abound.

The MDP literature is quite substantial. The early work of Bellman (1957) and Howard (1960) put the field on a firm footing. Later work synthesized the existing material and added new results. Textbooks by Puterman (1994) and Bertsekas (1995) give in-depth summaries. Contributions have been made by researchers in operations research, electrical engineering, dynamic programing, complexity theory, economics, algorithm analysis, artificial intelligence, and the behavioral sciences (see Chap. 1 of Puterman (1994) for a summary). Existing theory and algorithms have been applied successfully to real-world problems in a wide array of environments, and renewed attention in recent years has greatly expanded the range of problems to which this formalism can be applied.

Markov Models and Social Analysis

Lynne Billard, University of Georgia, Athens, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Many social science processes such as consumer behavior patterns, mobility patterns, friendship formations, networks, voting patterns, environmental management such as patient movements between hospitals are best analyzed by Markov models. Four specific examples are examined. Discrete time processes are called Markov chains, and continuous time processes are Markov processes. The basic models are described and some properties are provided.

Introduction

First-order Markov models are appropriate for analyzing social systems when the individual under study (person, system, unit, etc.) can be characterized as being in one of S (say) clearly identifiable states, and when the transition probabilities of moving from one state to another are dependent only on the current state (and not on any of the previous states; rth order models are those for which this dependence rests on the r most current states). Discrete time models give rise to Markov chains. Some basic properties are presented for time-homogeneous (stationary) and time-nonhomogeneous chains along with some inference procedures (maximum likelihood and empirical Bayes estimation). Also considered are continuous time Markov chains and Markov processes. Some results for the linear birth and death models (probabilities, holding times, etc.) are provided. Other related models such as the mover–stayer, mixed Markov, semi-Markov, and interactive Markov models are described briefly.

There are a plethora of social science processes that are best analyzed through the use of some form of Markov model. In a study of consumer behavior, individuals may switch from one brand of a product to another brand. Note that a 'change' here includes staying with the current brand, as well as the possibility of returning to a previously used brand. This switching can be 'random' over time, or the individual/customer may in time settle on a particular brand, or may even move away entirely from all brands to a different product. Likewise, voters may change their preferences for candidates from one party to another. Equivalently, workers may change jobs from one sector of the workforce to another; or the focus may be on intergenerational occupational patterns. Households, or individuals, may move across differing income levels or across various social classes. Credit card holders may move in and out of debt levels.

In a different direction, understanding (and predicting) bed occupancy rates in a hospital can be modeled by Markov processes. Instead of the movement of patients through the stages of illness recovery, the question of interest may be movement up the company's hierarchical promotion ladder(s) or on progress through states (or lack thereof, as in recidivism) in rehabilitation programs (as in health, criminology, etc.). Friendship formation and more generally network analyses and their various manifestations also fall under the Markov model rubric. Bartholomew (1983), among others, provides a compact summary and references for a wide array of applications.

A common thread in all such processes is that at a particular time, t say, the individual under study (i.e., person, system, etc.) is characterized as being in one of a number of clearly identifiable states, s say, $s = 1,\ldots, S$, where S is the total number of states. Another thread is that the state currently occupied by an individual depends on the state occupied at one or more previous times; that is, there is an underlying dependence between the observations. The data record these states for a set of individuals at times $t_0, t_1,\ldots, t_T$ where $T \geq 1$ and t_0 is the initial time. Time itself can be a discrete or continuous variable, leading to Markov chains or Markov processes, respectively (named after the Russian mathematician Andrei Andreevich Markov, 1856–1922, who developed fundamental probabilist results for dependent processes). When time is discrete, the data may typically be thought of as occurring at times $t = 0, 1,\ldots, T$ (with an implied assumption that changes from one time t to the next $(t + 1)$ are not dependent on the length of time between such measurements; this assumption is not always valid, see Section Finite State Markov Chains (*see* Longitudinal Data: Event–History Analysis in Discrete Time).

A first-order Markov chain, or simply a Markov chain, is characterized by the probabilities of moving from state i at time $t - 1$ to state j at time t, $p_{ij}(t)$, with

$$\begin{aligned} p_{ij}(t) &= P\left(\text{State } s = j \text{ at } t \middle| \text{State } s = i \text{ at } t-1\right) \\ &= P(s = j \text{ at } t | s = s_0 \text{ at } t = 0, \ldots, s = s_{t-2} \\ &\qquad \text{at } t-2,\ s = i \text{ at } t-1) \end{aligned} \quad [1]$$

that is, the transition probability depends only on its most recent state and not on the states occupied at other previous times. More generally, an rth order Markov chain is one for which the transition probabilities depend on the r most recent states. Except where specified, this article assumes a first-order chain as governed by [1]. These transition probabilities may be independent of t with $p_{ij}(t) \equiv p_{ij}$, which is the stationary (time-homogeneous) case, or may be a function of t giving rise to nonstationary (time-inhomogeneous) Markov chains. (Note that, for some users, stationarity defines the steady state or equilibrium probabilities obtained after a process has settled down; see Section Discrete Time Models: Markov Chains.) Homogeneity (or conversely, heterogeneity) refers typically to the fact that the transition probabilities are the same (or not the same) for all individuals in the study. Continuous time models

take two broad forms. The first is a finite state Markov chain based on eqn [1]. The other form falls under the heading of Markov processes characterized by transition rates $\lambda_{ij}(t)$ of moving from state i at time t to state j at the infinitesimal time later $t + \Delta t$ also independent of earlier transitions, i.e.,

$$P(s = j \text{ at } t + \Delta t | s = i \text{ at } t) = \lambda_{ij}(t) + o(\Delta t) \qquad [2]$$

where $o(\Delta t)/\Delta t \to 0$ as $\Delta t \to 0$. As for the Markov chain, these rates can be homogeneous (i.e., time-independent with $\lambda_{ij}(t) = \lambda_{ij}$) or nonhomogeneous. In these cases, it is more usual to focus attention on estimating the numbers in each state at time t rather than the transition probabilities of a single individual moving from one state to another; see Section Markov Processes. However, recently, a new approach was introduced by Billard and Dayananda (2014) in which, instead of focusing on the numbers in each state, the waiting time spent in each successive state was derived from which probabilities of movement to later states could be obtained.

Section Some Examples provides four examples of Markov models from the social science literature. The attention then shifts to the basic models and some of their properties, along with aspects of parameter estimation described in Sections Discrete Time Models: Markov Chains and Continuous Time Models: Markov Processes for discrete and continuous time models, respectively. Some extensions, such as mover–stayer models, mixed Markov models, semi-Markov models, and interactive Markov chains, are also covered briefly in Section Some Other Models.

Some Examples

Brand Loyalty

Manufacturers, and equally retailers, will always be interested in whether or not the users of their products remain loyal to a particular product and/or switch to another product, and if so, what it is that entices the loyalty/switch that occurs. Is this the effect of advertising, product quality, peer pressure, or what? Draper and Nolin (1964), Lawrence (1966) and Chatfield (1973), among others, first studied this behavior as a Markov chain. Suppose there are three products ($S = 3$): Brand A ($s = 1$), Brand B ($s = 2$), and Brand C ($s = 3$). Suppose the transition probabilities p_{ij}, $i, j = 1, 2, 3$, are as shown in **Table 1**, where it is assumed implicitly that these probabilities are constant over time. These p_{ij}'s represent the probability that an individual who bought one brand ($s = i$) at time ($t - 1$) will buy another brand ($s = j$) the next time (t). For example, the probability that a person who bought Brand A and then bought Brand B the next time is $p_{12} = 0.18$. The diagonal elements p_{ss}, $s = 1, 2, 3$, represent product loyalty; e.g., the probability that an individual bought Brand C both last time and this time is $p_{33} = 0.64$. Typically, in practice, these transition probabilities are unknown, and so must be estimated from data. Estimation procedures are discussed in Section Discrete Time Models: Markov Chains. Once these probabilities are known (or estimated), there are numerous questions of interest (e.g., what is the long-run brand loyalty over many time periods?) that can be answered; some of these will be presented in Section Discrete Time Models: Markov Chains.

Table 1 Brand-switching transition probabilities

		Time t		
	p_{ij}	*A*	*B*	*C*
Time ($t - 1$)	A	0.72	0.18	0.10
	B	0.09	0.85	0.06
	C	0.21	0.15	0.64

Occupational Mobility

Occupational mobility, or more broadly social mobility, can be modeled by a Markov chain. The data of **Table 2** display the probabilities associated with the son's (first) occupation and the occupation of the father. There are $S = 5$ possible occupations: self-employed and salaried professionals ($s = 1$); proprietors, clerical workers, and retail sellers ($s = 2$); craftsmen in manufacturing, construction, and other industries ($s = 3$); service workers, operatives, and laborers ($s = 4$); and farm managers and workers ($s = 5$). Thus, p_{ii}, $i = 1, \ldots, 5$, represents the probability of a son following his father's footsteps by going into the same occupation; e.g., the probability a son follows his father into farming is $p_{55} = 0.39$. The p_{ij}, $i \neq j$ represent the probabilities that the son goes into a different occupation; e.g., the probability a son goes into a self-employed position while his father worked as a construction worker is $p_{21} = 0.32$. The Biblarz and Raftery (1993) study was actually concerned with whether occupational mobility varied across race and/or across types of family disruption. Thus, instead of **Table 2**, there is a corresponding table for each of the demographic categories considered. Although it is beyond the scope of this article, logistic regression methods were used subsequently to study what factors most influenced occupational mobility, with the transition probabilities p_{ij} being the starting point.

In this example, changes in time t correspond to generational changes. Had the interest focused on occupational mobility of individuals over time (let us say, over decades), then data of the type of **Table 2** pertain but where now, e.g., $p_{31} = 0.19$ is the probability that an individual working in construction has moved into a self-employed or salaried professional position one decade later.

Instead of occupational mobility, states may represent social classes so that social mobility questions can be studied.

Table 2 Occupational mobility transition probabilities

Father's occupation	*Son's occupation*				
	1	*2*	*3*	*4*	*5*
1	0.48	0.18	0.11	0.22	0.01
2	0.32	0.24	0.11	0.31	0.02
3	0.19	0.16	0.21	0.42	0.02
4	0.13	0.15	0.13	0.55	0.04
5	0.09	0.08	0.09	0.35	0.39

Adapted from Biblarz, T.J., Raftery, A.E., 1993. The effects of family disruption on social mobility. American Sociological Review 58, 97–109.

Or, in a study of economic mobility, states would represent levels of economic status, be these states representing financial assets (say), credit-worthiness (say), income levels, or whatever economic factor is the focus. In all cases, the probabilities of movement from one state to another take the form of Table 2.

Voter Patterns

Anderson (1954), Goodman (1962), and Brown and Payne (1986), among numerous other authors, have used Markov chain models to study voting behavioral patterns. In Goodman's study, 455 potential voters were asked in six consecutive months which party's candidate would receive their vote, be that Republican (R, $s = 1$), Democrat (D, $s = 2$) or do not know (U, $s = 3$). Table 3(a) gives the numbers of those respondents who indicated in May how they would vote, and again what those responses were in June. Thus, for example, of the 445 subjects interviewed, 11 of those who in May did not know for whom they would vote had by June decided to vote for the Republican candidate. Or, equivalently, from the (estimated) transition probabilities of Table 3(b), 83% of those who in May planned to vote Democrat were still planning in June to vote for the Democrat candidate.

Malaria

Let us consider Cohen and Singer's (1979) study of malaria. Each individual was identified at time t as being in one of $S = 4$ states, corresponding to uninfected ($s = 1$), singly infected with *Plasmodium malariae* ($s = 2$), singly infected with *Plasmodium falciparum* ($s = 3$), or jointly infected with both *Plasmodium* species ($s = 4$). Eight surveys were conducted at regular (10-week) intervals, i.e., $T = 7$. The study also separately considered the transitions into and out of the four disease states, for each of seven age groups. Thus, for each age group, there is a 4×4 transition probability matrix (tpm) for each transition from time $t = t_u$ to $t = t_v > t_u$, of the type shown in Table 4 (extracted from Cohen and Singer, 1979), where t_u, $t_v = 0, \ldots, 7$. It is assumed that infection can occur at any time t and not just at those times surveyed, thus making this a continuous time Markov chain (in contrast to the previous examples, all of which were discrete time chains). In a different direction, Cohen and Singer (1979) also studied the malaria epidemic as a Markov process with transitions governed by eqn [2].

Table 3 Voting patterns

		(a)					(b)		
		June					June		
	#'s	R	D	U	Totals	p_{ij}	R	D	U

	3	0.39	0.01	0.53	0.07
	4	0.38	0.05	0.47	0.10

Discrete Time Models: Markov Chains

Stationary Markov Chains

Let $\mathbf{P}$ be an $S \times S$ matrix of transition probabilities $p_{ij}(t)$ (defined in eqn [1]), and let $p_{ij}(t) = p_{ij}$, i.e., the Markov chain is stationary. Note that $\sum_{j=1}^{S} p_{ij} = 1$. Let $p_s^{(0)}$ be the probability that an individual is in the initial state s at $t = 0$, $s = 1, \ldots, S$ and write $\mathbf{p}^{(0)}$ as the $S \times 1$ vector whose elements are $p_s^{(0)}$. The matrix $\mathbf{P}$ is called a tpm and $\mathbf{p}^{(0)}$ is the initial probability vector. The Markov chain is defined completely by $\mathbf{P}$ and $\mathbf{p}^{(0)}$ (*see* Probability Theory: Formal). Some basic results and definitions include the following.

1. The n-step-ahead probability matrix $\mathbf{P}^{(n)} = (p_{ij}^{(n)})$, $i, j = 1, \ldots, S$, and the n-step-ahead probability vector $\mathbf{p}^{(n)} = (p_i^{(n)})$, $i = 1, \ldots, S$, satisfy

$$\mathbf{P}^{(n)} = \mathbf{P}^n, \quad \mathbf{p}^{(n)} = \mathbf{p}^{(0)}\mathbf{P}^n \qquad [3]$$

where $\mathbf{P}^n$ implies matrix multiplication of $\mathbf{P}$ to the nth power in the usual way; and where the elements of $\mathbf{P}^{(n)}$ and $\mathbf{p}^{(n)}$, respectively, are $p_{ij}^{(n)}$, which is the probability that an individual in state i at time t is in state j at time $(t+n)$, and $p_i^{(n)}$, which is the probability the individual is in state i after n times units.

To illustrate, Table 5 provides the transition probabilities in $\mathbf{P}^{(2)}$ representing the probabilities associated with mobility between a grandfather's and a grandson's occupation, and were obtained from the $\mathbf{P}$ of Table 2. Thus, for example, the probability that both the grandfather and grandson are in farming is 0.1704. Note, however, that this says nothing about the father's occupation. Indeed, this term was calculated from

$$p_{55}^{(2)} = (0.09)(0.01) + (0.08)(0.02) + (0.09)(0.02) + (0.35)(0.04) + (0.39)(0.39) = 0.1704$$

Table 5 Two-generational transition probabilities

	Grandson's occupation				
Grandfather's occupation	1	2	3	4	5
1	0.3384	0.1810	0.1252	0.3321	0.0233
2	0.2934	0.1809	0.1268	0.3685	0.0304
3	0.2387	0.1708	0.1390	0.4176	0.0339
4	0.2102	0.1659	0.1332	0.4462	0.0445
5	0.1665	0.1335	0.1182	0.4114	0.1704

that is, the $p_{55}^{(2)}$ takes into account all possible occupations that the father might have had. The probability that all three generations were farmers is $(0.39)^2 = 0.1521$.

2. A state j is *accessible* from state i if and only if from some n, $p_{ij}^{(n)} > 0$. Note that i and j are not necessarily accessible in one step, but are accessible at some time $n > 0$. If no n exists for which $p_{ij}^{(n)} > 0$, then it is never possible to reach j from i. Two states, i and j, *communicate* with each other if each is accessible to the other.
3. If all states $\{1,\ldots, S\}$ communicate with each other, the chain is said to be *irreducible*.
4. If there exists an n such that $p_{ij}^{(n)} > 0$ for all i and j, then the chain is *ergodic*.
5. For an irreducible aperiodic ergodic chain, there exists a stationary distribution π, which satisfies $\pi = \pi\mathbf{P}$, with elements π_s representing the long-run proportion of times state s is visited and with $\sum \pi_s = 1$.

To illustrate with the brand-switching data of Table 1, it follows that $\pi = (0.299, 0.530, 0.171)$; i.e., in the long run, 29.9% of customers purchase Brand A, and likewise 53% (17.1%) selected Brand B (C).

There are innumerable other properties (*see* Probability Theory: Formal) that govern a Markov chain, providing answers to a wide range of questions of interest, such as whether or not a particular state or group of states is transient (i.e., eventual return is certain), absorbing (i.e., once reached cannot be exited), the expected number of visits to a state, and so forth. Details can be found in a variety of basic texts. All these properties evolve from a knowledge of the tpm $\mathbf{P}$ and the initial probability vector $\mathbf{p}^{(0)}$. Therefore, attention will now be directed to estimating these entities.

Statistical Inference-Classical Results

Suppose the data consist of N individuals, for each of whom it is known what state, X_{kt} say, that the kth person was in at each of the $t = 0, 1,\ldots, T$ time points recorded, $k = 1,\ldots, N$. For example, the X_{kt} may represent the brand of a product used by individual k at time t. It is assumed that $N > 1$, giving rise to the so-called panel studies. Let $n_s(0)$ be the number of individuals in state s at time $t = 0$. The $n_s(0)$ are assumed to be nonrandom; when they are random, the same results pertain except that the $n_s(0)$ are replaced by their expectations, $s = 1,\ldots, S$. Let $n_{ij}(t)$ be the number of individuals who moved from state i at time $t-1$ to state j at time t; and let $n_{ij} = \sum_{t=1}^{T} n_{ij}(t)$ be the total number of transitions from states i to j.

Then, the initial probabilities $p_s^{(0)}$, $s = 1,\ldots,S$, are estimated by

$$\widehat{p}_s^{(0)} = n_s(0) \Big/ \sum_{s=1}^{S} n_s(0). \qquad [4]$$

The maximum likelihood estimator (mle) of p_{ij}, $i, j = 1,\ldots, S$, is

$$\widehat{p}_{ij} = n_{ij} \Big/ \sum_{j=1}^{S} n_{ij} = \sum_{t=1}^{T} n_{ij}(t) \Big/ \sum_{t=1}^{T}\sum_{j=1}^{S} n_{ij}(t). \qquad [5]$$

When the Markov chain is not homogeneous, the mle of the transition probabilities $p_{ij}(t)$ is

$$\widehat{p}_{ij}(t) = n_{ij}(t)/n_{i.}(t), \quad t = 1,\ldots,T, \qquad [6]$$

where $n_{i.}(t) = \sum_{j=1}^{S} n_{ij}(t)$.

The transition probabilities for voter behavior from May to June given in Table 3(b) were estimated using eqn [5]. Estimated transition probabilities for each of the $T = 5$ transition times can be found by applying eqn [6] to Goodman's (1962) data (not shown).

For properties of these estimators and their original derivation, see Anderson and Goodman (1957). They also derived test statistics for key hypothesis testing and model validation situations. Further, these methods can be treated as special cases of log-linear models (see, e.g., Bishop et al., 1975) (*see* Multivariate Analysis: Discrete Variables (Overview)).

Empirical Bayes Estimation of P

When information from other similar data sets exists, that information can be incorporated into the estimation of the particular tpm $\mathbf{P}$ under discussion, by calculating an empirical Bayes estimator of $\mathbf{P}$. Not only does this utilize all the available information; the technique is especially useful when sample sizes are small, data are sparse, and/or mle's tend to take the extreme value of 0 or 1 for some p_{ij}. Thus, in a brand-switching scenario, data are available for each $l = 1,\ldots, L$ other locations (cities, stores, population sectors, etc.), and the location of particular interest is location $l = L + 1$. In effect, the p_{ij}'s of the tpm $\mathbf{P}_{L+1}$ for location $(L + 1)$ are assumed to have an underlying distribution whose unknown parameters are estimated by the data from the $\{l = 1,\ldots, L\}$ other chains; and thence through the use of Bayes' theorem and the data generated at the location $(L + 1)$, the tpm $\mathbf{P}_{L+1}$ can be estimated.

In this case, there are data values generated for $n_{ij}(t)$, n_{ij}, $n_s(0)$, $\mathbf{P}$, etc., for each $l = 1,\ldots, L, L + 1$. Then, the empirical Bayes estimate of the element p_{ij} of $\mathbf{P}_{L+1}$ is

$$\widehat{p}_{\mathrm{EB};ij} = \left(n_{ij}^* + \widehat{\rho}_{ij}\right) \Big/ \left(n_{i.}^* + \widehat{\rho}_{i+}\right), \quad i,j = 1,\ldots, S, \qquad [7]$$

where $n_{ij}^* \equiv n_{ij}$ and $n_{i.}^* \equiv n_i$ for location $L + 1$ and where $\widehat{\rho}_{i+} = \sum_{j=1}^{S} \widehat{\rho}_{ij}$. The $\widehat{\rho}_{ij}$ can be obtained by method of moments or maximum likelihood techniques. The method of moments estimate gives

$$\widehat{\rho}_{ij} = \overline{M}_{ij}\overline{X}_{ij} \big/ \left[\overline{M}_{ij}\left(1 - \overline{M}_{ij}\right) - \overline{X}_{ij}\right], \quad i, j = 1,\ldots,S, \qquad [8]$$

where

$$\overline{M}_{ij} = \frac{1}{L}\sum_{l=1}^{L} \overline{M}_{ijl}, \quad \overline{X}_{ij} = \frac{1}{L}\sum_{l=1}^{L} X_{ijl}$$

with

$$\overline{M}_{ijl} = n_{ijl}/n_{i.l}, \quad X_{ijl} = M_{ijl}\left(1 - M_{ijl}\right), \quad l = 1,\ldots,L.$$

The maximum likelihood estimate of $\widehat{\rho}_{ij}$ (and hence $\widehat{\rho}_{i+}$) are those values, which maximize the likelihood function

$$L\left(\rho_{ij}\middle|n_{ij}\right) \propto \frac{\Gamma(\rho_{i+})}{\Gamma\left(\rho_{ij} + n_{i..}\right)} \prod_{j=1}^{S} \frac{\Gamma(\rho_{ij} + n_{ij.})}{\Gamma\left(\rho_{ij}\right)} \qquad [9]$$

where $n_{ij.} = \sum_{l=1}^{L} n_{ijl}$, $n_{i..} = \sum_{j=1}^{S}\sum_{l=1}^{L} n_{ijl}$ and $\Gamma(\bullet)$ is the usual gamma function. Details of the derivation of the results

[7–9] can be found in Meshkani and Billard (1992), along with properties of these estimators and an example. When there is only a single Markov chain at each site (i.e., $N = 1$), the $\widehat{\rho}_{ij}$ and $\widehat{\rho}_{i+}$ are estimated differently; see Billard and Meshkani (1995).

Continuous Time Models: Markov Processes

Finite State Markov Chains

The Markov chains discussed in Section Discrete Time Models: Markov Chains were discussed in the context of discrete time. When there is a natural unit of time for which the data of a Markov chain process are collected, such as week, year, generational, etc., use of the discrete time model is satisfactory. If there is no natural time unit, then use of the discrete time model could be problematical. For example, for a given tpm $\mathbf{P}$, does the corresponding tpm for 1 year later equal $\mathbf{P}^{(2)}$, or $\mathbf{P}^{(12)}$, for a time unit of 6 months, or 1 month, respectively? Clearly, the answers are different though the time period – 1 year later – is the same. Such difficulties can be circumvented by using a continuous time Markov chain; see Singer and Spilerman (1975), and Shorrocks (1978). When time is continuous, the concepts elucidated for the discrete time chains carry over though the notation and some of the mathematics differ.

Let X_t represent the state of the chain at time t, and let

$$p_{ij}(t) = P(X_{t+t_0} = j | X_{t_0} = i) \qquad [10]$$

be the elements of the $S \times S$ matrix $\mathbf{P}(t)$ with $\sum_{j=1}^{S} p_{ij}(t) = 1$ for all $i = 1,\ldots, S$. Then, for continuous times t_1 and $t_2 \geq 0$, the $\mathbf{P}(t)$ satisfy

$$\mathbf{P}(t_1 + t_2) = \mathbf{P}(t_1)\mathbf{P}(t_2) \qquad [11]$$

or, equivalently,

$$p_{ij}(t_1 + t_2) = \sum_{k=1}^{S} p_{ik}(t_1)p_{kj}(t_2). \qquad [12]$$

The eqns [11] and [12] are called the Chapman–Kolmogorov equations. These equations are used to show that the matrix $\mathbf{P}(t)$ satisfies the differential equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{P}(t) = \mathbf{Q}\mathbf{P}(t) \qquad [13]$$

where $\mathbf{Q}$ is an $S \times S$ matrix whose elements q_{ij} satisfy

$$\begin{aligned} q_{ij} &= \lim_{\Delta t \to 0} p_{ij}(\Delta t)/\Delta t, \quad i \neq j, \\ q_{ii} &= \lim_{\Delta t \to \infty} [1 - p_{ii}(\Delta t)]/\Delta t, \quad i = j, \end{aligned} \qquad [14]$$

and are called *intensities*. It follows that

$$q_{ii} = -\sum_{i=1, i\neq j} q_{ij} \equiv -q_i, \text{ say.} \qquad [15]$$

Then, $(-q_{ij}/q_i)$ represents the conditional probability that an individual in state i moves to state j given a transition occurred, and $(-1/q_i)$ is the average time an individual stays in state i.

Eqn [13] can be solved to give

$$\mathbf{P}(t) = \mathbf{e}^{\mathbf{Q}t} = \sum_{n=0}^{\infty} \mathbf{Q}^n t^n / n! = \mathbf{U}\mathbf{A}(t)\mathbf{U}^{-1} \qquad [16]$$

where $\mathbf{A}(t) = (\mathrm{diag}(e^{\lambda_i t}))$, $i = 1,\ldots, S$, is the $S \times S$ diagonal matrix with $\{\lambda_i\}$ being the eigenvalues of $\mathbf{Q}$, and where $\mathbf{U}$ is the $S \times S$ matrix of the eigenvectors of $\mathbf{Q}$.

Conditions (on the $p_{ij}(t)$ values), most notably embeddability and identifiability problems, which allow the solution in eqn [16] to exist have received considerable study. Singer and Spilerman's (1976) lengthy article provides a nice summary as well as extensive insights. In a series of papers (see, e.g., Stasny, 1986), movement in and out of the labor force entirely embodies these principles (where the $S = 3$ states represent those who are: employed, unemployed, and not in the labor force). Geweke et al. (1986) expand upon these difficulties within the context of mobility models. Some conditions include the following, where $\widehat{\mathbf{P}} = (\widehat{p}_{ij})$ is the observed estimate of $\mathbf{P}$ obtained by the methods of Section Discrete Time Models: Markov Chains.

1. If $S = 2$, $\widehat{p}_{ij} \geq 0$, $\widehat{p}_{i1} + \widehat{p}_{i2} = 1$, $i = 1, 2$, if and only if $\widehat{p}_{11} + \widehat{p}_{22} > 1$.
2. If $\widehat{p}_{ij}(t) = 0(\neq 0)$, then $\widehat{p}_{ij}^{(n)} = 0(\neq 0)$, for all (respectively, any) integers n.
3. The determinant $|\mathbf{P}| > 0$.
4. Other than the first eigenvalue ($\lambda_1 = 1$ always) no other λ_i equals one and any negative λ_i has even multiplicity.

Markov Processes

Markov processes are continuous time Markov models based on eqn [2], where the focus is on the number of individuals in a given state at time t (rather than the transitions probabilities). The two simplest such models are the so-called Poisson process and the birth and death models. Let $X_s(t)$ be the number of individuals in state s at time t, $s = 1,\ldots, S$.

The possible transitions can be visualized as movements in and out of compartments

$$\begin{aligned} &|\overline{s = 0}| \to \ldots \rightleftarrows |\overline{s = i}| \rightleftarrows \ldots \\ &\rightleftarrows |\overline{s = j}| \rightleftarrows \ldots \to |\overline{s = S}| \end{aligned} \qquad [17]$$

i and j at transition rates $\lambda_{ij}(t)$; see eqn [17]. It is assumed that two or more transitions do not occur simultaneously, and that transitions in different time intervals occur independently. Typically, the number of compartments S is finite. In many applications, the total size of the population $\sum_{s=1}^{S} X_s(t) = N$ is bounded at N. When N is unknown (or unbounded) as in a pure birth process (say, which has $S = 1$ state corresponding to the size of the population represented by the number of births), then in the context of [17], the 'source' of new births can be thought of as transitions from a hypothetical state $s = 0$. Similarly, a hypothetical state $s = S^* = S + 1$ can be incorporated if necessary. Thus, for a birth and death process, $S = 1$, but births correspond to transitions from an $s = 0$ state and deaths reflect transitions from $s = 1$ to a state $s = S^* = 2$. Markov processes are governed by a system of differential-difference equations obtained from the basic Chapman–Kolmogorov

relations [12]. To illustrate, for a birth and death process, these equations become

$$\frac{\mathrm{d}}{\mathrm{d}t}p_x(t) = -(\lambda_x + \mu_x)p_x(t) + \lambda_{x-1}p_{x-1}(t) + \mu_{x+1}p_{x+1}(t), \quad x = 1, 2, \ldots, \qquad [18]$$

$$\frac{\mathrm{d}}{\mathrm{d}t}p_0(t) = -\mu_0 p_0(t) + \mu_1 p_1(t), \quad x = 0,$$

where

$$p_x(t) = P[X(t) = x|X(0) = a] \qquad [19]$$

and where λ_x and μ_x are the transition rates of births and deaths, respectively, given the population is of size $X(t) = x$. The initial conditions are $p_a(0) = 1$ and $p_x(0) = 0$ for $x \neq a$.

When the birth and death rates are linearly proportional to the population size, i.e., when $\lambda_x = \lambda x$ and $\mu_x = \mu x$, say, then the solution is, for $a = 1$, and $\lambda \neq \mu$,

$$p_x(t) = \begin{cases} (1-\alpha)(1-\beta)\beta^{x-1}, & x \geq 1, \\ \alpha, & x = 0, \end{cases} \qquad [20]$$

where

$$\alpha = \mu(\delta - 1)/(\lambda\delta - \mu), \quad \beta = \lambda(\delta - 1)/(\lambda\delta - \mu)$$

$$\delta = \exp[(\lambda - \mu)t].$$

Thus, when $x \geq 1$, the population size is modeled by a geometric distribution.

When $\lambda = \mu$ and $a = 1$,

$$p_x(t) = \begin{cases} (\lambda t)^{x-1}/(1+\lambda t)^{x+1}, & x \geq 1, \\ (\lambda t)/(1+\lambda t), & x = 0. \end{cases} \qquad [21]$$

In the particular case that the birth rate is a constant (i.e., $\lambda_x = \lambda$) and the death rate is zero (i.e., $\mu_x = 0$), the solution of eqn [18] gives

$$p_x(t) = P[X(t) = x] = e^{-\lambda t}(\lambda t)^x/x!, \quad x = 0, 1, \ldots, \qquad [22]$$

where, without loss of generality, $a = 0$. This is the Poisson process. An implication of these results is that the waiting time between occurrences of events is exponentially distributed. Thus, in the Poisson process, the average waiting time between events (whose total number follows a Poisson distribution) is $(1/\lambda)$.

In the linear birth and death process, the average size of the population at time t is

$$E\{X(t)\} = \begin{cases} a\delta, & \lambda \neq \mu, \\ a, & \lambda = \mu, \end{cases} \qquad [23]$$

with variance

$$\mathrm{Var}\{X(t)\} = \begin{cases} a\delta(\delta-1)(\lambda+\mu)/(\lambda-\mu), & \lambda \neq \mu, \\ 2a\lambda t, & \lambda = \mu. \end{cases} \qquad [24]$$

The average waiting time for a birth, or a death, to occur given that a transition does occur is $\lambda_x/(\lambda_x + \mu_x)$, or $\mu_x/(\lambda_x + \mu_x)$, respectively. The probability of eventual extinction is 1 if $\lambda \leq \mu$, and $(\mu/\lambda)^a$ if $\lambda > \mu$.

Corresponding results for a pure linear birth (or death) process can be obtained by substituting $\mu = 0$, (or $\lambda = 0$, respectively), in eqns [18], [20], [23], and [24].

When there are S states, the system of eqn [18] is generalized as follows. Let $\mathbf{X}(t) = ((X_1(t), \ldots, X_S(t))$ be the random variable representing the number of individuals in each state $s = 1, \ldots, S$, at time t. Let $p_{\mathbf{x}}(t) = P(\mathbf{X}(t) = \mathbf{x}|\mathbf{X}(0) = \mathbf{a})$, where $\mathbf{x} = (x_1, \ldots, x_s)$ is a specific value of $\mathbf{X}(t)$. Write $x_{ij} = (x_1, \ldots, x_i + 1, \ldots, x_j - 1, \ldots, x_s)$, i.e., $x_i \equiv x_i + 1$ and $x_j \equiv x_j - 1$ and all other $x_k \equiv x_k$; and likewise for the $\lambda_{ij}(t)$. Then, the Markov process is governed by the system of differential equations

$$\frac{\mathrm{d}}{\mathrm{d}t}p_x(t) = -\sum_{i,j=1}^{S} \lambda_{ij}(t)p_x(t) + \sum_{i,j=1, i\neq j} \lambda_{i+1,j-1}p_{x_{ij}}(t) \qquad [25]$$

for x in the S-dimensional space of possible values. Typically, there exist some boundary conditions on one or more of the values x_s, $s = 1, \ldots, S$, which necessitate a separate equation for that x_s value. This occurred in the linear birth and death process modeled in eqn [18], when $x = 0$. Models for which $S > 1$ are sometimes called interactive Markov models.

In general, except when the transition rates $\lambda_{ij}(t)$ are both independent of time and linear (in one only of i and j, but not in both, such as when, e.g., $\lambda_{ij}(t) = \lambda i$ but not λij), the existence and derivation of solutions to eqn [25] are nontrivial tasks. However, when all the transitions across states flow in the same direction, i.e., when in [2], $\lambda_{ij}(t) = 0$ for all $j < i$ to give the so-called right-shift process (or, equivalently, a left-shift process if $\lambda_{ij}(t) = 0$ for all $i < j$), then the recursion theorem of Severo (1969) can be applied successfully to obtain the underlying state probabilities from which all other properties can be obtained. Although written in the context of the progression of HIV to AIDS, Billard and Zhao (1994) give a general solution for time-dependent transitions moving to the next state, $j = i + 1$. Nevertheless, the solutions are still computationally intensive.

Unfortunately, since many applications have nonlinear transition rates, these difficulties cannot be dismissed lightly. For example, the spread of epidemics and rumors is modeled invariably with nonlinear rates. For simplicity, suppose $S = 3$ with states $s = 1$, $s = 2$, and $s = 3$ corresponding, respectively, to the number of susceptibles, infectives, and removals (either by recovery, death, immunity, etc.). Then, the rate that a susceptible person becomes infected is proportional to both the number of susceptible people and the number of infective people; thus $\lambda_{12}(t) = \beta x_1 x_2$ (where β is the infection rate), and is a nonlinear function of the underlying variables. More generally, there may be several stages of infection and/or removals, leading to an $S > 3$. The spread of rumors and news propagation corresponds to infection spread. Likewise, friendship formations, and indeed network systems and population modeling more generally, typically have nonlinear rates and are modeled as Markov processes.

If it is known that ultimately (as time t extends to ∞) steady-state conditions prevail, then, the derivatives in eqn [18] or [25] become $\mathrm{d}p_x(t)/\mathrm{d}t \equiv 0$ with $P_x(t) \equiv P_x$. The resulting equations can then be solved quite easily to obtain expressions for p_x. Notice these do not provide information about the process at specific times t before the steady-state conditions occur.

Some authors have attempted to work with the deterministic versions of the stochastic eqn [25]. In this case, instead of the probabilities $p_x(t)$, the $\mathbf{X}(t)$ are set as fixed rather than

random variables, and these $\mathbf{X}(t)$ replace the $p_x(t)$ in eqn [25]. Great care is needed here. While the solution to the deterministic equations equals the expected value of the stochastic variable when the λ_{ij} are linear rates, the equivalence does *not* hold for nonlinear transition rates. However, the deterministic result may provide a reasonable approximation when the population size increases to infinity ($N \to \infty$) for a fixed time t. This does not hold in the reverse case (as $t \to \infty$ for fixed N). Bartholomew (1984) and Lehoczky (1980) provide an excellent discussion of this issue.

Some Other Models

It can happen for a specific social process and/or a particular data set that a unique feature exists, which precludes the direct application of the basic Markov model as described thus far. This gives rise to models, which are still Markovian in nature but have an added characteristic.

One such model is the mover–stayer model, in which the population consists of two subgroups, the movers and the stayers. The movers are individuals who move (with nonzero probability) between the states according to a Markov chain process, while the stayers are those who always stay in their initial state. Thus, if θ is the proportion of stayers in state s, $s = 1,\ldots, S$, then the transition probability of moving from state i at t to state j at $t + n$ is

$$p_{ij}^{*} = \theta_i \delta_{ij} + \left(1 - \theta_i\right) p_{ij}^{(n)} \qquad [26]$$

where $p_{ij}^{(n)}$ is the n-step-ahead transition probability (found from eqn [3]) and δ_{ij} is the Kronecker delta ($\delta_{ij} = 0$ if $i \neq j$, and 1 if $i = j$). The $p_{ij}^{(n)}$ are estimated by the methods of Section Discrete Time Models: Markov Chains. The mle estimator of θ_s is

$$\widehat{\theta}_s = 1 - \left[1 - n_s \widehat{p}_{ss}^{T} \big/ n_s(0)\right] \Big/ \left(1 - \widehat{p}_{ss}^{T}\right) \qquad [27]$$

where $\widehat{p}_{ss}$ is the mle estimator of p_{ss}, $n_s(0)$ is the number of individuals in states s at time $t = 0$, and n_s is the number of individuals (stayers) who were in state s for all times $t = 0, 1,\ldots, T$; see Frydman (1984). Sampson (1990) considers a restricted model and illustrates the model with data describing movement of men across seven employment sectors.

While the mover–stayer model accommodates some heterogeneity, more generally there may be K subpopulations. The underlying process consists of a mixture of K Markov chains giving rise to a mixed Markov chain model. Thus, a mover–stayer model is the special case that $K = 2$, and that one of the tpm's is the identity matrix $\mathbf{I}$. Vogel (1996) considers a mixture of $K = 2$ populations, those who do and those who do not enter into extensive plea bargaining in the criminal setting. In a mixed model, individuals can only move within their own subpopulation. When they are able to move out of one subpopulation into another, the model becomes a latent Markov chain model. See Langeheine and Pol (1990) for a detailed discussion of these models.

A semi-Markov model is one that is specified by both the transition probabilities ($\mathbf{P}$ as in a Markov chain) and the distribution (specifically the parameters) of the length of time R_{ij} an individual stays in a state i before moving to state j, $i, j = 1,\ldots, S$ (which need not equal the geometric waiting time distribution of the standard Markov chain). Note that transitions and waiting times depend only on the current state and are conditionally independent of previously visited states; see, e.g., Weiss et al. (1982).

Conclusion

This article has described briefly the basic principles underlying Markov models. Markov models are particularly useful to describe a wide variety of behavior such as consumer behavior patterns, mobility patterns, friendship formations, networks, voting patterns, environmental management (e.g., patient movement between hospital stations), etc., among innumerable other applications in the social sciences. Four particular examples have been provided herein. The article also included brief summaries of how data governed by these Markov processes can be assessed and modeled. The texts by Bartholomew (1981, 1982) and Bartholomew and Forbes (1979), along with the review articles by Anderson (1954), Goodman (1962), Singer and Spilerman (1976), and Cohen and Singer (1979), among others, provide more extensive details of these models and their applications.

Markov Processes in Learning Spaces

Jean-Claude Falmagne, University of California, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A learning space is a family of sets satisfying certain conditions. The sets are called knowledge states. In the most common application of these concepts, a knowledge state is a set of items of knowledge, such as all the concepts mastered by a student in some part of mathematics. Two applications of Markov processes to learning spaces are described. The most important one is the core component of an assessment system designed to uncover the knowledge state of the student by systematic questioning. A learning space can also be used as a teaching instrument. The student masters the items one by one, progressively increasing the size of his or her knowledge state. The second Markov process is a stochastic mechanism tracking the gradual learning of an item.

A *knowledge structure* is a family $\mathscr{K}$ of subsets of a basic set Q of *items* of knowledge. The set Q is called the *domain* of the knowledge space. The sets in $\mathscr{K}$ are the *knowledge state*, or simply the *states*. It is assumed that both the empty set $\varnothing$ and the domain Q are states. A knowledge structure is *finite* if its domain is finite.

As our typical example, we take Q to be the set of all the types of problems forming a curriculum in beginning algebra. Each state K in $\mathscr{K}$ represents a possible competence of a student in beginning algebra: the student in state K has mastered all the items in K and none of the items in Q, K. A student in state $\varnothing$ does not know anything in beginning algebra; a student in state Q has mastered the full curriculum in that subject. A knowledge structure is a *knowledge space* if it is closed under finite union, that is, for any two subsets K and L of Q, if both K and L are in $\mathscr{K}$, then so is $K \cup L$. A *learning space* is a special case of a knowledge space playing an important role in education. This concept is discussed in Sections The Learning Spaces and A Miniature Example.

Two Markov-type processes are used in the practical application of these concepts. One is the core component of the *assessment engine* designed to uncover the knowledge state of a student by systematic questioning (see Section The Assessment Engine). The other is a Markov mechanism monitoring the gradual learning of an item by a student (see Section The Learning Engine). Section Evaluating the Efficiency of the System reviews some methods used to evaluate the efficiency of the algorithms. Background material and references are covered in Section Background and References.

The Learning Spaces

An important special case of knowledge structures are the *learning spaces*. A knowledge structure $\mathscr{K}$ on a domain Q is a *learning space* if it satisfies the following two principles:

[L1] Learning Smoothness. If K and L are two states such that $K \subset L$, then there exists a finite chain of states $K_0 = K \subset K_1 \subset \ldots \subset K_n = L$ such that $|K_{i+1}, K_i| = 1$, for $0 \leq i \leq n-1$.

In words: *Stepwise learning is possible. Any knowledge state can be reached from a less advanced state by mastering the items one by one.*

[L2] Learning Consistency. If K and L are two states satisfying $K \subset L$ and $q \in Q, K$ is an item such that $K \cup \{q\} \in K$, then $L \cup \{q\} \in K$.

In words: *If a student is capable of mastering an item, then a student in a more advanced state may already have mastered this item. Otherwise, that more advanced student must also be capable of mastering it.*

However obvious these two principles may seem from an educational standpoint, they put severe constraints not only on the structure, but also on the choice of the items and the manner of writing them.

Note that a learning space is necessarily a finite knowledge structure. Indeed, because both $\varnothing$ and Q are states, principle [L1] requires that there be a finite chain $K_0 = \varnothing \subset K_1 \subset \ldots \subset K_m = Q$, with $|K_{i+1}, K_i| = 1$, for $0 \leq i \leq m-1$. This implies that $|Q| = m$. It can be shown that any learning space is a knowledge space, that is, it is closed under union.

While actual knowledge structures are typically very large, numbering millions of states, they are in fact relatively small in comparison with the set of all subsets of the domain. In the case of our example of beginning algebra, the curriculum contains about 350 types of algebra problems that a student must master. This means that the size of the domain Q is 350. So, the number of subsets of Q is 2^{350}. The proportion of such subsets that are states is minuscule.

The two principles [L1] and [L2] have important consequences. A critical one is that any state can be represented accurately by its two *fringes*, which are typically much smaller sets. So, the fringes are an efficient summary of a state.

The *outer fringe* of a state K in a learning space $\mathscr{K}$ is the set K^{o} of all items in Q, K such that, for any q in K^{o}, the set $K \cup \{q\}$ is also a state of $\mathscr{K}$. Such a state $K \cup \{q\}$ is thus a possible immediate successor of the state K in a learning sequence. Assuming that the learning space is an accurate representation of the cognitive organization of the items, we can interpret the outer fringe of a state K as the set of all those items that a student in that state is *ready to learn*.

The *inner fringe* of a nonempty state K is the set K^{I} of all items q in K such that the set $K\{q\}$ is also a state of $\mathscr{K}$. Such a state $K\{q\}$ is thus a possible immediate predecessor of the state K. The outer fringe and the inner fringe of a state are thus corresponding concepts.

A Miniature Example

We illustrate the concepts of learning space and outer fringe by an example using five items in beginning algebra, labeled *a*, *c*, *g*, *h*, and *i*, which are described in Table 1. These five items form a miniature learning space that is part of the considerably larger learning space currently used by several hundred thousand students in the United States and abroad (see Section Background and References). This miniature learning space is pictured by the graph of Figure 1.

Each ellipse of this graph represents one of the 16 knowledge states in that learning space. The blank circle at the top stands for the empty state. Learning proceeds from top to bottom, the items being mastered successively. So, the arrows represent the precedence relation between the states. The items *a* and *c* form the *outer fringe* of the state pictured by the red ellipse. This state contains the items *g*, *h*, and *i*. The outer fringe is made of the items that the student is *ready to learn*. The *inner fringe* of that state is made of the items *g*, *h*, and *i*. Each of these items could be the last one that the student has mastered. In

Table 1 Five items in beginning algebra with an instance

Item	*One sample instance*[a]
a. Quotients of expressions involving exponents	Simplify the following: $\frac{a^4 b^5}{5a^6 b}$
c. Plotting a point in the coordinate plane using a virtual pencil on a Cartesian graph	Using the pencil, plot the point $(-4, 7)$.
g. Multiplication of a decimal by a whole number	Multiply. $\begin{array}{r} 2.95 \\ \times \quad 5 \\ \hline \end{array}$
h. Integer addition (introductory problem)	$-4 + 4 = \square \quad -7 + 5 = \square \quad -3 + (-4) = \square$
i. Equivalent fractions	Fill in the blank to make the two fractions equivalent: $\frac{3}{5} = \frac{\square}{15}$

[a]An instance is a particular case of an item.

Figure 1 Miniature learning space on the items *a*, *c*, *i*, *g*, and *h*.

Figure 2 Graph of the learning space of 50 items in beginning algebra, in the style of the five-item graph of **Figure 1**. Every point in the graph represents a state. The colors of the lines linking the states correspond to the various subtopics of beginning algebra. The graph of **Figure 1** is a small portion of this graph, with its circles represented by points here. Drawing the full graph of the 350 items of beginning algebra is impractical. Reproduced from figures in Chapters 1 and 2 of Falmagne et al. (2013), with permission of the publisher.

this simple case, the inner fringe is the same as the whole state, but this is rarely the case in realistic learning spaces.

The five items are listed in Table 1, together with one exemplary *instance* of each item. An instance is a special case of an item. Typically, there are thousands of instances for each item. Whenever an item is used in an assessment, one instance is randomly selected and proposed to the student. These five items are part of a collection of 350 items in beginning algebra.

Drawing the same type of graph for the whole of beginning algebra, which contains about 350 items, is not only daunting but also actually impractical. Some idea of the difficulty is conveyed by the graph of Figure 2, which represents the learning space of just 50 items in beginning algebra.

Yet, the assessment engine and the learning engines of the system are capable of efficiently managing such enormous structures, and in fact the much larger structure of the full beginning algebra and similar scholarly curricula.

Figure 4 Initial probabilities of all the states at the beginning of the assessment. The likelihood is marked by the shading of the circles representing the states. Bluish black means very unlikely, and bright yellow means very likely. Reproduced from figures in Chapters 1 and 2 of Falmagne et al. (2013), with permission of the publisher.

The Assessment Engine

The task of the assessment engine is to uncover, by efficient questioning, the knowledge state of a student under examination. As the number of items in a typical learning space is large, only a small part of the items can be asked, in practice, in any assessment. So, the successive questions must be cleverly chosen. The procedure follows a scheme outlined in Figure 3.

Figure 3 Diagram of the transitions in the assessment procedure. Four successive operations are involved: the selection of a maximally informative item, the choice of an instance, the recording of the student's response and its verification, and the updating of the likelihood distribution.

It has two main components: the *questioning rule* and the *updating rule*.

At the outset of the assessment, each knowledge state is assigned a certain initial probability, which may depend upon the school year of the student, if it is known, or on some other information. These initial probabilities represent how much the assessment engine knows about the student before any question is asked. They play no role in the final result of the assessment but may be helpful in shortening it.

These initial probabilities are pictured on the graph on the left by colors varying from reddish to yellow. Except that the ellipses are circles here, this graph is similar to that of Figure 1, which is in fact part of it. So, each circle represents a state. This graph represents a learning space on the 10 items *a*, *b*, …, *j*, five of which are described in Table 1. The color of each circle represents the probability of the corresponding state. The full color scale indicated at the bottom of the graph goes from bluish black for very unlikely to bright yellow for very likely. The somewhat lighter colors of some circles show that the system thinks the student might have mastered about five to seven items.

The system then asks an instance of the first item, which is chosen to be as informative as possible, on the basis of the current probabilities of the states. The adopted rule is to ask the student an item that has about a 50% chance of eliciting a correct response, on the basis of the current probabilities.

Suppose that the first item asked is *a*, and the student's response is correct. The updating rule will then increase the probabilities of all the states containing *a* and decrease the probabilities of all those states not containing *a*. This is pictured by the leftmost graph of Figure 5 in which the colors of the circles are brightened and darkened accordingly. If the next item asked is *f* and the response is incorrect, the updating rule will then decrease the probabilities of the state containing *f* and increase the probabilities of the states not containing *f*. The middle graph pictures the result of such an updating. At the end, the situation may be as pictured by the graph on the right. Only one state remains with a very high probability. The system will then choose the state containing *a*, *b*, *g*, *h*, and *i* as being the current state of the student.

We now give the formal description of the stochastic process. For details, see Falmagne and Doignon (2011, Chapter 13).

Figure 5 On the left, the effect of a correct response to item *a* on the state's probabilities is marked by brightening the yellow shades for states containing *a* and darkening those shades for those states not containing *a*. The graph in the middle depicts the subsequent effect of an incorrect response to item *f*. The graph on the right represents a possible situation at the end of the assessment. The assessment engine will pick the state containing *a*, *b*, *g*, *h*, and *i* as being the current state of the student. Reproduced from figures in Chapters 1 and 2 of Falmagne et al. (2013), with permission of the publisher.

Basic Concepts

Given a learning space $\mathscr{K}$ on a domain Q, any assessment is a realization of a Markovian stochastic process. We use the following notation:

n	the step number, or *trial* number, $n = 1, 2, \ldots$;
$\mathscr{K}_q$	the subcollection of $\mathscr{K}$ containing all the states containing q;
Λ_+	the set of the positive probability distributions on $\mathscr{K}$;
$\mathbf{L}_n$	a random probability distribution on $\mathscr{K}$; we have $\mathbf{L}_n = L_n \in \Lambda_+$ (so $L_n > 0$) if L_n is the probability distribution on $\mathscr{K}$ at the beginning of trial n;
$\mathbf{L}_n(K)$	a random variable measuring the probability of state K on trial n;
$\mathbf{Q}_n$	a random variable representing the question asked on trial n; we have $\mathbf{Q}_n = q \in Q$ if q is the question asked on trial n;
$\mathbf{R}_n$	a random variable coding the response on trial n: $\mathbf{R}_n = \begin{cases} 1 & \text{if the response is correct} \\ 0 & \text{otherwise} \end{cases}$
$\mathbf{W}_n$	the random history of the process from trial 1 to trial n;
ι_A	the indicator function of a set A: $\iota_A(q) = \begin{cases} 1 & \text{if } q \in A \\ 0 & \text{if } q \notin A \end{cases}$;
$\zeta_{q,r}$	with $1 < \zeta_{q,r}$ for $q \in Q$, $r = 0, 1$ a family of parameters specifying the updating operator (see Axiom [U] following).

The process begins, on trial 1, by setting $\mathbf{L}_1 = L \in \Lambda_+$. So, the initial probability distribution is the same for any realization. Any further trial $n > 1$ begins with a value $L_n \in \Lambda_+$ of the random distribution $\mathbf{L}_n$ updated as a function of the event on trial $n-1$. We write for any $\mathscr{F} \subseteq \mathscr{K}$,

$$L_n(\mathscr{F}) = \sum_{K \in \mathscr{F}} L_n(K). \qquad [1]$$

Three general axioms specify the stochastic process ($\mathbf{L}_n$, $\mathbf{Q}_n$, $\mathbf{R}_n$). The version of these axioms given below is an important special case.

[U] **Updating Rule.** We have $\mathbb{P}(\mathbf{L}_1 = L) = 1$, and for any positive integer n, with $\mathbf{L}_n = L_n$, $\mathbf{Q}_n = q$, $\mathbf{R}_n = r$, and

$$\zeta_{q,r}^K = \begin{cases} 1 & \text{if } \iota_K(q) \neq r, \\ \zeta_{q,r} & \text{if } \iota_K(q) = r, \end{cases} \qquad [2]$$

we have

$$L_{n+1}(K) = \frac{\zeta_{q,r}^K L_n(K)}{\sum_{K' \in \mathscr{K}} \zeta_{q,r}^{K'} L_n(K')}. \qquad [3]$$

This updating rule is called *multiplicative with parameters* $\zeta_{q,r}$.

[Q] **Questioning Rule.** For all $q \in Q$ and all positive integers n,

$$\mathbb{P}(\mathbf{Q}_n = q | \mathbf{L}_n, \mathbf{W}_{n-1}) = \frac{\iota_{S(L_n)}(q)}{|S(L_n)|}$$

where $S(L_n)$ is the subset of Q containing all those questions q minimizing

$$|2L_n(\mathscr{K}_q) - 1|.$$

Under this questioning rule, which is called *half-split*, we must have $\mathbf{Q}_n \in S(L_n)$ with a probability equal to 1. The questions in the set $S(L_n)$ are then chosen with equal probability.

[R] **Response Rule.** For all positive integers n,

$$\mathbb{P}(\mathbf{R}_n = \iota_{K_0}(q) | \mathbf{Q}_n = q, \mathbf{L}_n, \mathbf{W}_{n-1}) = 1$$

where K_0 is the *latent state* representing the set of all the items mastered by the student, that is, the state that must be uncovered by the Markovian procedure.

So, if the item selected by the process belongs to the latent state K_0, the probability of a correct response is equal to 1. In the more realistic versions of this axiom used in practice, one additional parameter is used that specifies the probability of a *careless error*. It may also be necessary to introduce a *lucky guess* parameter, for example, if a multiple choice paradigm is used.

Some Key Results

These results follow from axioms [U], [Q] and [R]. (For proofs, see Chapter 13 in Falmagne and Doignon, 2011.)

1. The updating operator specified by eqn [3] in axiom [U] is essentially a Bayesian operator. This can be shown by an appropriate transformation of the equation.
2. This updating operator is *permutable*. This term is used in the functional equations literature (Aczél, 1966) to designate a function F satisfying the equation

$$F(F(x, y), z) = F(F(x, z), y).$$

This property is essential because it means that the order of the questions has no import on the result of the assessment.

3. The stochastic process ($\mathbf{L}_n$) is Markovian.
4. The stochastic process ($\mathbf{L}_n$) converges to the latent state K_0 in the sense that

$$\mathbf{L}_n(K_0) \xrightarrow{\text{a.s.}} 1$$

(in which 'a.s.' means 'almost surely').

Remark. Another Markovian assessment procedure was also developed, which is based on a very different principle (Falmagne and Doignon, 1988b). The stochastic process is a finite Markov chain, the states of which are subsets of the domain Q of the learning space.

The Learning Engine

An important mathematical consequence of the two principles [L1] and [L2] defining a learning space is that, at the end of an assessment, the knowledge state is completely specified by its two fringes. In practice, the student is only given the list of items in the outer fringe of his or her knowledge state. These are the items that the student is *ready to learn*. This list can be shorter if the *intermediate objectives* feature of the system is used, which permits the teacher to establish a preferred progression of major topics. In such a case, the system gives the students only the part of the outer fringe that is consistent with the next intermediate objective.

The Random Walk Tracking Mechanism

In any event, the student chooses the next item to learn. This initiates the *Markovian Tracking Mechanism* illustrated by Figure 6. This system guides the student's progress. It monitors the sequence of successes and failures of the student in attempting to solve the successive instances of the item chosen via a random walk.

The student enters the random walk at the red point and is given an instance of the problem. In case of a failure to solve that instance, the student is given an explanation $\boxed{E}$ of the solution. A new instance of the problem is then presented. When the student gives a correct response to an instance, a new instance is also given. The random walk evolves until hitting one of the two absorbing barrier states represented by the blue and black dots in Figure 6. If the blue dot state is reached, the system decides that the problem is learned and the student leaves the random walk. The knowledge state of the student is then adjusted upward. On the other end, if the random walk hits the black dot state, the system decides that the item cannot be in the outer fringe of the student. The student leaves the random walk and either the knowledge state is reevaluated or a new assessment is triggered (depending on the cases). Because the items proposed to the students are picked in the outer fringe of the student's state, the proportion of failure is small in practice (see #2 in Section Evaluating the Efficiency of the System).

Evaluating the Efficiency of the System

Two evaluation methods have been used:

1. The extra question. In each assessment, an extra question is asked that is not used to determine the knowledge state. The student's response to the extra question can be predicted from the uncovered knowledge states. The correlation between the student's actual response to the extra question and the response predicted from the knowledge state uncovered is noticeably higher than similar statistics obtained in standardized tests.
2. The learning success probability. One may reasonably ask: what is the probability that the student successfully masters an item chosen in the outer fringe? In other words, what is the probability that the sequential tracking mechanism pictured in Figure 6 has the student end up at the blue exit (success) point?

The estimated median probability is .92. This value has been estimated on the basis of a very large number of learning occasions (see Section Background and References). What is meant by 'learning occasion' is that the student picks an item in the outer fringe, gets an instance, and starts learning. Statistics show that in later assessments, a student is capable of solving an instance of learned item in about 75% of the cases, which is high considering that different instances of the same item are typically used, and that careless errors are unavoidable. These numbers are based on the analysis of hundreds of thousands of learning occasions and assessments.

A third possibility may come to mind. We can mimic standardized testing and transform the state into a numerical score. This can be done simply by counting the number of items in the state uncovered by the assessment. The objection is that, in most cases, there are many thousand states having the same number of items. Collapsing all these states into the same numerical score results in a huge loss of information. Still, when such a collapse is performed, the predictive power of the numerical score is better than that of a standardized test such as the S.A.T. or the A.C.T. (see Ahlgren and Harper, 2011).

Background and References

The monograph by Falmagne and Doignon (2011) comprehensively presents the theory of knowledge spaces, and their important special case, the learning spaces. The

Figure 6 The random walk tracking mechanism with two absorbing states represented by the blue and the black dots. Reproduced from figures in Chapters 1 and 2 of Falmagne et al. (2013), with permission of the publisher.

theoretical developments of knowledge space theory were supported by several National Science Foundation (NSF) grants and one Department of Defense grant to Falmagne, first at New York University and later at the University of California, Irvine (UCI). The mathematical results supporting the stochastic assessment mechanism outlined in this article were published in Falmagne and Doignon (1988a). The basic idea of the updating algorithm was prompted by the Markovian learning models initiated by W.K. Estes (1950), and by R.R. Bush and F. Mosteller (1951). More specifically, the updating operator specified by eqn [3] was inspired by the *beta learning model* of Luce (1959). Other relevant references are Bush and Mosteller (1955), Estes and Suppes (1957), and Suppes and Ginsburg (1963). A general study of the Markov processes underlying all these learning models is presented in Norman (1972). For a general presentation of the mathematical theory of Markov processes, see Bharucha-Reid (1960). A description of some of the applications of knowledge spaces and some further theoretical development is contained in Falmagne et al. (2013).

The development of the educational software implementing the assessment engine and the learning engine on the Internet was supported by a large NSF grant to Falmagne at UCI. This software covers K12 mathematics and basic chemistry. It belongs to UCI and was licensed to the Aleks Corporation. ALEKS is an acronym for Assessment and LEarning in Knowledge Spaces. It is also the name of the software itself. Since its inception in 1999, the system has been used by millions of students in more than four thousand K12 schools, colleges, and universities not only in the United States, but also in Europe, Australia, and Latin America (the Aleks system is bilingual English–Spanish).

Maroons in Anthropology

Richard Price, College of William & Marry, Williamsburg, VA, USA

Abstract

Maroons – self-liberated slaves and their descendants – still form semi-independent communities in several parts of the Americas, for example, Suriname, French Guiana, Jamaica, Colombia, Belize, and Brazil. As the most isolated of Afro-Americans, they have since the 1920s been an important focus of anthropological research, contributing to theoretical debates about slave resistance, the heritage of Africa in the Americas, the process of creolization, and the nature of historical knowledge among nonliterate peoples.

Maroons – self-liberated slaves and their descendants – still form semi-independent communities in several parts of the Americas, for example, Suriname, French Guiana, Jamaica, Colombia, Belize, and Brazil. As the most isolated of Afro-Americans, they have since the 1920s been an important focus of anthropological research, contributing to theoretical debates about slave resistance, the heritage of Africa in the Americas, the process of creolization, and the nature of historical knowledge among nonliterate peoples.

Maroons and Their Communities

The English word 'Maroon' derives from Spanish *cimarrón* – itself based on an Arawakan (Taino) Indian root. *Cimarrón* originally referred to domestic cattle that had taken to the hills in Hispaniola, and soon after it was applied to American Indian slaves who had escaped from the Spaniards. By the end of the 1530s, the word was being used primarily to refer to Afro-American runaways. Communities formed by Maroons dotted the fringes of plantation America, from Brazil to Florida, from Peru to Texas. Usually called *palenques* in the Spanish colonies and *mocambos* or *quilombos* in Brazil, they ranged from tiny bands that survived less than a year to powerful states encompassing thousands of members that lasted for generations or even centuries.

Marronage became a response to enslavement in Africa as well, in the wake of the internecine wars fostered by the Atlantic slave trade. Fugitives from the chaos and violence that dominated much of West Central Africa, including runaways from slave coffles during the seventeenth- and eighteenth-century expansion of the trade, frequently founded Maroon settlements in marginal areas. Some had populations of several hundreds, lived by raiding more settled groups, or even fought against their former masters. But all remained sufficiently caught up in the political ebb and flow of the era that they did not maintain separate Maroon identities for more than a generation or two. During the eighteenth century, fugitives from the trade along the Upper Guinea coast also formed Maroon communities, sometimes on islands just offshore, but mass recapture after months or years was the norm.

In the Americas, the meaning and attractiveness of marronage differed for enslaved people in different social positions, varying with their perceptions of themselves and their situations, which were influenced by diverse factors such as their places of birth, the periods of time they had been in the New World, their task assignments as slaves, their family responsibilities, and the particular treatments they were receiving from overseers or masters, as well as more general considerations such as the proportions of blacks to whites in the region, the proportions of freedmen in the population, the natures of available terrain in which to establish communities, and the opportunities for manumission. Many Maroons, particularly men, escaped during their first hours or days in the Americas. Enslaved Africans who had already spent some time in the New World seem to have been less prone to flight. But Creole slaves who were particularly acculturated, who had learned the ways of the plantation best, seem to have been highly represented among runaways, often escaping to urban areas where they could pass as free because of their independent skills and ability to speak the colonial language.

The large number of detailed newspaper advertisements for runaway slaves placed by masters attests to the high level of planter concern, while at the same time affording the critical historian an important set of sources for establishing the profiles of Maroons, which varied significantly by historical period and country. Individual Maroons fled not only to the hinterlands – many, especially skilled slaves, escaped to urban centers and successfully melted into the population of freedmen – but also became maritime Maroons, fleeing by fishing boat or other vessel across international borders. In Haiti, Maroons played a signal role as catalysts in the Haitian Revolution (1791) that created the first nation in the Americas in which all citizens were free.

During the past several decades, anthropological fieldwork has underlined the strength of historical consciousness among the descendants of these rebel slaves and the dynamism and originality of their cultural institutions. Meanwhile, historical scholarship on Maroons has flourished, as new research has done much to dispel the myth of the docile slave. Marronage represented a major form of slave resistance, whether accomplished by lone individuals, by small groups, or in great collective rebellions. Throughout the Americas, Maroon communities stood out as an heroic challenge to white authority, as the living proof of the existence of a slave consciousness that refused to be limited by the whites' conception or manipulation of it. It is no accident that throughout the Caribbean today, the historical Maroon – often mythologized into a larger-than-life figure – has

become a touchstone of identity for the region's writers, artists, and intellectuals, the ultimate symbol of resistance and the fight for freedom.

Maroons and their communities can be seen to hold a special significance for the study of Afro-American societies. For while they were, from one perspective, the antithesis of all that slavery stood for; they were also a widespread and embarrassingly visible part of these systems. Just as the very nature of plantation slavery implied violence and resistance, the wilderness setting of early New World plantations made marronage and the existence of organized Maroon communities a ubiquitous reality.

Planters generally tolerated *petit marronage* – truancy with temporary goals such as visiting a friend or lover on a neighboring plantation. But in most slave-holding colonies, the most brutal punishments – amputation of a leg, castration, suspension from a meat hook through the ribs, slow roasting to death – were reserved for long-term, recidivist Maroons, and in many cases these were quickly written into law. Marronage on the grand scale, with individual fugitives banding together to create communities, struck directly at the foundations of the plantation system, presenting military and economic threats that often taxed the colonists to their very limits. Maroon communities, whether hidden near the fringes of the plantations or deep in the forest, periodically raided plantations for firearms, tools, and enslaved women, often permitting families that had formed during slavery to be reunited in freedom.

To be viable, Maroon communities had to be inaccessible, and villages were typically located in remote, inhospitable areas. In the southern United States, isolated swamps were a favorite setting, and Maroons often became part of Native American communities. In Jamaica, some of the most famous Maroon groups lived in the intricately accidented 'cockpit country,' where water and good soil are scarce but deep canyons and limestone sinkholes abound. In the Guianas, seemingly impenetrable jungles provided Maroons with a safe haven.

Successful Maroon communities learned quickly to turn the harshness of their immediate surroundings to their own advantage for purposes of concealment and defense. Paths leading to the villages were carefully disguised, and much use was made of false trails replete with dangerous booby traps. In the Guianas, villages set in swamps were approachable only by an underwater path, with other, false, paths carefully mined with pointed spikes or leading only to fatal quagmires or quicksand. In many regions, man traps, or even dog traps, were used in village defenses.

Throughout the hemisphere, Maroons developed extraordinary skills in guerrilla warfare. To the bewilderment of their colonial enemies, who attempted to employ rigid and conventional tactics learned on the open battlefields of Europe, these highly adaptable and mobile warriors took maximum advantage of confined environments, striking and withdrawing with great rapidity, making extensive use of ambushes to catch their adversaries in cross fire, fighting only when and where they chose, depending on reliable intelligence networks among non-Maroons (both slaves and white settlers), and often communicating by drums and horns.

In many cases, the beleaguered colonists were eventually forced to sue their former slaves for peace. In Brazil, Colombia, Cuba, Ecuador, Hispaniola, Jamaica, Mexico, Panama, Peru, Suriname, and Venezuela, for example, the whites reluctantly offered treaties granting Maroon communities their freedom, recognizing their territorial integrity, and making some provision for meeting their economic needs, in return for an end to hostilities toward the plantations and an agreement to return future runaways. Of course, many Maroon societies were crushed by massive force of arms, and even when treaties were proposed they were sometimes refused or quickly violated. Nevertheless, new Maroon communities seemed to appear almost as quickly as the old ones were exterminated, and they remained, from a colonial perspective, the 'chronic plague' and 'gangrene' of many plantation societies right up to final emancipation.

Today, the relationships between Maroon communities and the nation-states in which they live vary broadly. In much of Brazil or even Jamaica, communities remain proud of their Maroon heritage but, to an outsider, seem little different from the non-Maroon rural population that surrounds them. In contrast, along the rivers of Suriname, Maroons live in villages that outsiders often compare to precolonial Africa, where everything from language, dress, kinship, transportation, and laws are unique Maroon creations that instantly differentiate the population from others in the country. The tension between Maroon identity and national identity has become acute for many younger people who have moved from traditional territories to cities or even to foreign countries. Yet in some areas, such as the Saamaka villages along the Suriname river, both Maroon culture and identity remain vibrant.

African Origins, New World Creativity

The initial Maroons in any New World colony hailed from a wide range of societies in West and Central Africa – at the outset, they shared neither language nor other major aspects of culture. Their collective task, once off in the forests or mountains or swamplands, was nothing less than to create new communities and institutions, largely via a process of inter-African cultural syncretism. Those scholars, mainly anthropologists, who have examined contemporary Maroon life most closely seem to agree that such societies are often uncannily 'African' in feeling but at the same time largely devoid of directly transplanted systems. However 'African' in character, no Maroon social, political, religious, or aesthetic *system* can be reliably traced to a specific African ethnic provenience – they reveal rather their hybrid composition, forged in the early meeting of peoples of diverse African, European, and Amerindian origins in the dynamic setting of the New World (Price, 2008).

The political system of the great seventeenth-century Brazilian Maroon kingdom of Palmares, for example, which R.K. Kent has characterized as an 'African' state, "did not derive from a particular Central African model, but from several" (in Price, 1996:188). In the development of the kinship system of the Ndyuka Maroons of Suriname, writes André Köbben, "undoubtedly their West-African heritage played a part … [and] the influence of the matrilineal Akan tribes is unmistakable, but so is that of patrilineal tribes … [and there are] significant differences between the Akan and Ndyuka

matrilineal systems" (in Price, 1996:324). Historical and anthropological research has revealed that the magnificent woodcarving of the Suriname Maroons, long considered 'an African art in the Americas' on the basis of formal resemblances, is in fact a fundamentally new, Afro-American art 'for which it would be pointless to seek the origin through direct transmission of any particular African style' (in Price, 1996:29). Detailed investigations – both in museums and in the field – of a range of cultural phenomena among the Saamaka Maroons of Suriname have confirmed the dynamic, creative processes that continue to animate these societies (Price and Price, 1999; Price, 2008).

Maroon cultures do possess direct and sometimes spectacular continuities from particular African peoples, from military techniques for defense to recipes for warding off sorcery. These are, however, of the same type as those that can be found, albeit with lesser frequency, in Afro-American communities throughout the hemisphere. In stressing these isolated African 'retentions,' there is a danger of neglecting cultural continuities of a more significant kind. Roger Bastide divided Afro-American religions into those he considered 'preserved' or 'canned' – like Brazilian *Candomblé* – and those that he considered 'alive' – like Haitian *Vaudou*. The former, he argued, manifest a kind of 'defense mechanism' or 'cultural fossilization,' a fear that any small change may bring on the end, while the latter are more secure of their future and freer to adapt to the changing needs of their adherents (in Price, 1996:29). Indeed, tenacious fidelity to 'African' forms seems, in many cases, to indicate a culture finally having lost meaningful touch with the vital African past. Certainly, one of the most striking features of West and Central African cultural systems is their internal dynamism, their ability to grow and change. The cultural uniqueness of the more developed Maroon societies (e.g., those in Suriname) rests firmly on their fidelity to 'African' cultural principles at these deeper levels – whether aesthetic, political, religious, or domestic – rather than on the frequency of their isolated 'retentions.' With a rare freedom to extrapolate ideas from a variety of African societies and adapt them to changing circumstances, Maroon groups included (and continue to include today) what are in many respects at once the most meaningfully African and the most truly 'alive' and culturally dynamic of all Afro-American cultures (Price, 2008).

Six Cases

The most famous Maroon societies are Palmares in Brazil, Palenque de San Basilio in Colombia, the communities in Esmeraldas, Ecuador, the Mexican Maroons of San Lorenzo de los Negros, the Maroons of Jamaica, and the Saamaka and Ndyuka Maroons of Suriname. (For further readings on these communities, see Price, 1996.)

Palmares, in northeastern Brazil, flourished for a full century before its final defeat by a large Portuguese army in 1694–95. A close-knit federation of villages made up of some 11 000 people, largely Angolan-born Africans; it also included Brazilian Indians, poor whites, and Portuguese deserters. During the seventeenth century, wave after wave of Dutch and then Portuguese armies was sent out against Palmares, which resisted with the help of its complex political and social organization, under the leadership of Ganga Zumba and, during its final years, the legendary Zumbi. Knowledge of the internal affairs of Palmares remains limited, based as it is on soldiers' reports, the testimony of a captive under torture, official documents, archaeological work, and the like. But as a modern symbol of black (and anticolonial) heroism, Palmares continues to evoke strong emotions in Brazil.

Palenque de San Basilio boasts a history stretching back to the seventeenth century. In recent years, historians, anthropologists, and linguists – working in collaboration with Palenqueros – have uncovered a great deal about continuities and changes in the life of these early Colombian freedom fighters, whose proud descendants still occupy the town today.

The Maroon history of Esmeraldas, on the Pacific coast of Ecuador, and neighboring Barbacoas in Colombia, began in the early sixteenth century, when Spanish ships carrying African slaves from Panama to Guayaquil and Lima were wrecked amidst strong currents. A number of slave survivors sought freedom in the unconquered interior, where they allied with indigenous peoples. In the 1580s, having beaten back military expeditions sent to capture them, several Maroon leaders traveled to Quito to make peace with the Spanish. In 1599, a famous portrait of one such leader, Don Francisco de Arobe, and his two sons, was commissioned and sent to Philip III of Spain to commemorate these negotiations. Later, these Maroons were joined by rebel slaves from highland *haciendas* and lowland mines and formed a number of free towns, even as slavery continued nearby.

San Lorenzo de los Negros, in Veracruz on the Caribbean coast of Mexico, is probably the best known of the seventeenth-century Maroon towns in Mexico. Under their leader Yanga, these Maroons attempted to make peace as early as 1608, but it was not till 1630, after years of intermittent warfare, that the Viceroy and the crown finally agreed to establish the town of free Maroons.

The Jamaica Maroons, who continue to live in two main groups centered in Accompong (in the hills above Montego Bay) and in Moore Town (deep in the Blue Mountains), maintain strong traditions about their days as freedom fighters, when the former group was led by Cudjoe and the latter by the redoubtable woman warrior Nanny (whose likeness now graces the Jamaican 500 dollar bill). Two centuries of scholarship, some of it written by Maroons themselves, offers diverse windows on the ways these men and women managed to build a vibrant culture within the confines of a relatively small island.

The Suriname Maroons now constitute the most fully documented case of how former slaves built new societies and cultures, under conditions of extreme deprivation, in the Americas and how they developed and maintained semi-independent societies that persist in the present. From their late seventeenth-century origins and the details of their wars and treaty making to their current struggles with multinational mining and timber companies, much is now known about these peoples' achievements, in large part because of the extensive recent collaboration by Saamaka and Ndyuka Maroons with anthropologists. Today, Suriname Maroons – who number some 122 000 people – live in the interior of the country, in and around the capital Paramaribo, and in neighboring French Guiana as well as in the Netherlands. The relevant bibliographic resources now number in the

thousands – useful points of entry are Price and Price (1999) and Thoden van Velzen and van Wetering (2004).

Anthropological Issues

Since Melville and Frances Herskovits's first foreign fieldwork, with Saamaka Maroons during the summers of 1928 and 1929, Maroons have moved to the center of anthropological debates, from the origins of Creole languages and the 'accuracy' of oral history to the nature of the African heritage in the Americas and the very definition of Afro-American anthropology.

The Saamaka fieldwork played a signal role in Melville Herskovits's career, exercising – in the words of his widow – "a profound influence on his thinking. … In the Guiana bush… he saw, as he often told his students, nearly all of sub-Saharan Africa represented, from what is now Mali to Loango and into the Congo – and the Loango chief who came to our base camp [in Saamaka territory] invoked both the Great God of the Akan of the Gold Coast, Nyankompon, and the Bantu Zambi" (Herskovits, 1966:vii–viii). During that Maroon research, and on the voyages to and from Suriname, Herskovits developed a comparative vision of Afro-American studies (and of the Caribbean as 'a social laboratory') that would fuel his own prodigious work, and that of countless students, for decades to come. The seeds of his interest in exploring the African provenience of New World Negroes, in establishing an historical-ethnographic baseline in Africa for the study of New World developments, and in analyzing processes of cultural change (such as 'acculturation,' 'reinterpretation,' and 'syncretism') were all sown during this early fieldwork.

The expansion and critique of Herskovits' work, especially the controversial essay by Sidney W. Mintz and Richard Price (1992) and the reactions to it, have kept Maroons at the center of debate among Afro-Americanist anthropologists and historians (Price, 2006). Indeed, David Scott argues that the Saamaka Maroons have by now become "a sort of anthropological metonym … providing the exemplary arena in which to argue out certain anthropological claims about a discursive domain called Afro-America" (1991:269).

Much of the recent anthropological research among Maroons has focused on historiography and historical consciousness – how Maroons themselves conceptualize and transmit knowledge about the past – and it has privileged the voices of individual Maroon historians. *First-Time* presented oral historical accounts by Saamakas of the early years of their society's formation, 300 years ago, including their rebellions from slavery and their battles against the colonists (Price, 2002 (orig. 1983)). *Alabi's World* supplemented these Saamaka accounts with archival materials from German missionaries and Dutch administrators who lived in Saamaka villages beginning right after the 1762 peace treaties with the colonists, directly juxtaposing ever more complex written and oral materials about the same events (Price, 1990). *True-Born Maroons* combined oral and archival materials, with an emphasis on the perspective of Maroons themselves, for Jamaica, uncovering a remarkable number of African practices as well as a great deal of early New World creolization, involving language, religious practices, and much else (Bilby, 2005). A recent history in Dutch of the first century of Ndyuka Maroons presents alternating chapters based on oral and archival materials, creating a rich historical picture of politics and social life in this Suriname Maroon society (Thoden van Velzen and Hoogbergen, 2011).

Taken together, these studies helped pioneer the complementary use of oral history and archival research in anthropology more generally. They have caused significant chinks in traditional historians' reluctance to take oral data as seriously as written materials. Not surprisingly, this type of work has occasionally raised the charge of 'verificationism' from post-modernist scholars (Scott, 1991) but the particular kinds of attention it shows to the politics of memory – the strategic use of archival materials to complement Maroon narratives – can be defended as a decisive and progressive political act, one intended in part to foster social justice, rather than being judged naive or politically retrograde (Price, 2006).

Recent anthropological research has also focused on the ongoing debate about 'creolization' and the extent to which (and the ways in which) Maroons and other African-Americans have drawn, on the one hand, upon their diverse African heritages and, on the other hand, upon their New World experiences and their own creativity in building their cultural worlds. Researchers have been asking how, in each New World colony, enslaved Africans, coming from a variety of nations and languages, became African-Americans. Scholars have found that to begin to explore these processes, across the many regions where Africans were landed as captive laborers, one must first ask: How 'ethnically' homogeneous (or heterogeneous) were the Africans who arrived in a particular New World locality – in other words, to what extent was there a clearly dominant group – and what were the cultural consequences? How quickly and in what ways did they and their African-American offspring begin thinking and acting as members of new communities? In what ways did the African arrivants choose – and to what extent were they able – to continue particular ways of thinking and doing things that came from the Old World? What did 'Africa' (or its subregions and peoples) mean at different times to African arrivants and their descendants? How did the various demographic profiles and social conditions of particular New World settings encourage or inhibit these cultural processes? In short, what is it that made what Haitian anthropologist Michel-Rolph Trouillot calls 'the miracle of creolization' possible, across the Americas, over and over again?

Maroon societies play a privileged role in such discussion, in part owing to their relative isolation and, in the case of Suriname, their persistence into the present. The most detailed ethnography of creolization to date (Price, 2008) analyzes extensive data from esoteric Maroon languages, as well as other ritual materials, to demonstrate the complexity of these issues from both an ethnohistorical perspective and that of Maroons themselves. Eric Hobsbawm, commenting on the significance of this kind of work in the more general context of the social sciences, notes that "Maroon societies raise fundamental questions. How do casual collections of fugitives of widely different origins, possessing nothing in common but the experience of transportation in slave ships and of plantation slavery, come to form structured communities? How, one might say more generally, are societies founded from scratch? What exactly did or could

such refugee communities … derive from the old continent?" (1990:46). Questions such as these are sure to keep students of Maroon societies engaged in active research for many years to come.

Since the turn of the twenty-first century, Maroons have taken center stage in the struggle for territory and sovereignty within nation-states, particularly in Brazil and in Suriname. Following promulgation of the new constitution of Brazil in 1988 (and subsequent reforms), the descendants of historical *quilombos* (which originally meant 'Maroon communities') have, under certain conditions, had the right to claim collective title to the lands on which their ancestors lived. In the process of the ensuing legal battles, the definition of *quilombo* has expanded to include almost any landless black Brazilian community – rural or urban – whose members can claim a history of resistance to state power – not just descendants of Maroons. Today, many young Brazilian anthropologists are trained explicitly to help such *quilombo*-descendant communities in their quest for title to lands and related rights.

In 1990s' Suriname, the Saamaka Maroons – some 55 000 people – found the lands that their ancestors had lived on since the late seventeenth century invaded by Chinese loggers and other multinational mining and extraction companies that had received permits from the national government. Suriname's constitution grants ownership of the forest, which is inhabited by a number of indigenous peoples as well as six Maroon peoples, to the State, which during that decade began doling out mining and logging concessions to foreign multinationals. Organizing themselves and obtaining legal aid, the Saamaka People fought a decade-long legal battle with the Republic of Suriname. This struggle culminated in a landmark 2007 judgment by the Inter-American Court for Human Rights (the case of *Saramaka People v Suriname*), requiring the nation to change its laws to grant the Saamaka people collective title to their traditional territory as well as considerable sovereignty over it – a judgment that establishes jurisprudence for indigenous peoples and Maroons throughout the Americas. Richard Price served as advisor and expert witness for the Saamaka during this case, providing an example of advocacy in anthropology. The case and its significance are discussed in detail in Price (2011).

Abstract

David Courtnay Marr was born in 1945 in Essex, England. Marr's dissertation, written at Trinity College, Cambridge and published between 1969 and 1971, presented a theory of mammalian brain function, parts of which remain relevant to the present day, despite vast advances in neurobiology in the past decades. In 1973, Marr joined the Artificial Intelligence Laboratory at the Massachusetts Institute of Technology, where he was made a tenured full professor in 1980. Marr died in November 1980, of leukemia. His highly influential book, *Vision: A Computational Investigation into the Human Representation and Processing of Visual Information*, which has redefined and revitalized the study of human and machine vision, was published posthumously, in 1982, with a new edition appearing in 2010.

David Courtnay Marr was born on 19 January 1945 in Essex, England. He attended Rugby, the English public school, on a scholarship and went on to Trinity College, Cambridge. By 1966, he obtained his BS and MS in mathematics and proceeded to work on his doctorate in theoretical neuroscience, under the supervision of Giles Brindley. Having studied the literature for a year, Marr commenced writing his dissertation. The results, published in the form of three journal papers between 1969 and 1971, amounted to a theory of mammalian brain function, parts of which remain relevant to the present day, despite vast advances in neurobiology in the past four decades. Marr's theory was formulated in rigorous terms, yet was sufficiently concrete to be examined in view of the then available anatomical and physiological data. Between 1971 and 1972, Marr's attention shifted from general theory of the brain to the study of vision. In 1973, he joined the Artificial Intelligence Laboratory (AI Lab) at the Massachusetts Institute of Technology (MIT) as a visiting scientist, taking on a faculty appointment in the Department of Psychology in 1977, where he was made a tenured full professor in 1980. In the winter of 1978, he was diagnosed with acute leukemia. David Marr died on 17 November 1980, in Cambridge, Massachusetts. His highly influential book, *Vision: A Computational Investigation into the Human Representation and Processing of Visual Information*, which has redefined and revitalized the study of human and machine vision, was published posthumously, in 1982. A new edition (MIT Press, 2010) includes an introduction by Shimon Ullman and a postface by Tomaso Poggio, two of Marr's closest collaborators.

A Theory of the Brain

Marr's initial work in neuroscience combined high-level theoretical speculation with meticulous synthesis of the anatomical data available at the time. The question he chose to address is the *nec plus ultra* of neuroscience: what is it that the brain does? Marr proposed a definite answer to this question for three major brain structures: archicortex (the phylogenetically older part of the cerebral cortex), cerebellum, and neocortex. The three answers complement each other, rallying around the idea that the brain's central function is statistical pattern recognition and association, carried out in a very high-dimensional space of 'elemental' features. The basic building block of all three theories is a *codon*, or a subset of features, with which there may be associated a cell, wired so as to fire in the presence of that particular codon.

In the first paper, Marr proposed that the cerebellum's task is to learn the motor skills involved in performing actions and maintaining posture (Marr, 1969). The Purkinje cells in the cerebellar cortex, presumably implementing the codon representation, associate (through synaptic modification) a particular action with the context in which it is performed. Subsequently, the context alone causes the Purkinje cell to fire, which in turn precipitates the next elemental movement. Although the cerebellum is now seen as only a part of the brain-action learning and control system (which involves, notably, a number of functional loops linking it with the cortex, the hippocampus, the basal ganglia, and the thalamus), Marr's ideas regarding its computational role are still considered essentially correct.

The next paper (Marr, 1970) extended the codon theory to encompass a more general kind of statistical concept learning, which he assessed as "capable of serving many of the aspects of the brain's function" (the vagueness of this aspect of the theory would lead him soon to abandon this approach, which, as he realized all along, was "once removed from the description of any task the cerebrum might perform"). How can a mere handful of techniques for organizing information (such as the codon representation) support a general theory of the brain function? Marr's views in this matter were profoundly realist, and were based on a postulate of "the prevalence in the world of a particular kind of statistical redundancy, which is characterized by a 'Fundamental Hypothesis,'" stating that "Where instances of a particular collection of intrinsic properties (i.e., properties already, diagnosed from sensory information) tend to be grouped such that if some are present, most are, then other useful properties are likely to exist, which generalize over such instances. Further, properties often are grouped in this way" (Marr, 1970, pp. 150–151). This worldview and the ideas that it engendered presaged much of the later work by others on neural network models of brain function, which invoke the intuition of learning as optimization ('mountain climbing') in an underlying probabilistic representation space.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61085-1

A model at whose core is the tallying of probabilities of events needs an extensive memory of a special kind, allowing retrieval based on the content, rather than the storage location, of the items. Marr's third theoretical paper considered the hippocampus as a candidate for fulfilling this function (Marr, 1971). In analyzing the memory capacity and the recall characteristics of the hippocampus, Marr integrated abstract mathematical (combinatorial) constraints on the representational capabilities of codons with concrete data derived from the latest anatomical and electrophysiological studies. The paper postulated the involvement in learning of synaptic connections modifiable by experience – a notion originating with the work of Donald Hebb (*see* Hebb, Donald Olding (1904–1985)) in the late-1940s and discussed by Marr's mentor Brindley in a 1969 paper. Marr provided a mathematical proof of efficient partial content-based recall by his model and offered a functional interpretation of many anatomical structures in the hippocampus, along with concrete testable predictions. Many of these (such as the existence in the hippocampus of experience-modifiable synapses) were subsequently corroborated (see the reviews in Vaina, 1990).

The MIT Period

A consummation of this three-prolonged effort to develop an integrated mathematical–neurobiological understanding of the brain would in any case have earned Marr a prominent place in a gallery, spanning two and a half centuries (from John Locke (*see* Locke, John (1632–1704)) to Kenneth Craik) of British Empiricism, the epistemological stance perennially popular with neuroscientists. As it were, having abandoned the high-theory road soon after the publication of the hippocampus paper, Marr went on to make his major contribution to the understanding of the brain by essentially inventing a field and a mode of inquiry: *computational neuroscience*. By 1972, the focus of his thinking in theoretical neurobiology shifted away from abstract theories of entire brain systems, following a realization that without an understanding of specific tasks and mechanisms – the issues from which his earlier theories were 'once removed' – any general theory would be glaringly incomplete.

Marr first expressed these views in public at an informal workshop on brain theory, organized in 1972 at the Boston University by Benjamin Kaminer. In his opening remarks, he suggested an 'inverse square law' for theoretical research, according to which the value of a study varies inversely with the square of its generality – an assessment that favors top-down reasoning anchored in functional (computational) understanding, along with bottom-up work grounded in an understanding of the mechanism, but not theories derived from intuition, or models built on second-hand data.

The new methodological stance developed by Marr following the shift in his views is summarized in a remarkably lucid and concise form in a two-page book review in *Science*, titled "Approaches to Biological Information Processing" (Marr, 1975). By that time, Marr came to believe firmly that the field of biological information processing had not yet accrued an empirical basis sufficient for guiding and supporting a principled search for a general theory. Remarking that the brain may turn out to admit "of no general theories except ones so unspecific as to have only descriptive and not predictive powers" – a concern echoed in one of his last papers (Marr, 1981) – he proceeded to mount a formidable critique of the most common of the theories circulated in the early 1970s, such as catastrophe theory and neural nets (the current popularity of dynamical systems approaches and of connectionism, taken along with the integration of Marr's critical views into the mainstream theoretical neurobiology, should fascinate any student of the history of ideas).

The main grounds for his argument, which was further shaped by an intensive and fruitful interaction with Tomaso Poggio (Marr and Poggio, 1977), were provided by an observation that subsequently grew into a central legacy of Marr's career: the understanding of any information processing system is incomplete without insight into the problems it faces, and without a notion of the form that possible solutions to these problems can take. Marr and Poggio termed these two levels of understanding *computational* and *algorithmic*, placing them above the third, *implementational*, level, which, in the study of the brain, refers to the neuroanatomy and neurophysiology of the mechanisms of perception, cognition, and action.

Upon joining the MIT AI Lab, Marr embarked on a vigorous research program seeking computational insights into the working of the visual system, and putting them to the test of implementation as computer models. Marr's thinking in the transitional stage, at which he treated computational results on par with neurobiological findings, is exemplified by the paper on the estimation of lightness in the primate retina (Marr, 1974); subsequently, much more weight was given in his work to top-down, computational-theory considerations. This last period in Marr's work is epitomized by the theory of binocular stereopsis, developed in collaboration with Poggio, and presented in a series of ground-breaking papers (Marr and Poggio, 1976, 1979). At that time, Marr also worked on low-level image representation (Marr, 1976; Marr and Hildreth, 1980), and on shape and action categorization (Marr and Nishihara, 1978; Marr and Vaina, 1982). Marr's book, *Vision*, written during the last months of his life, is as much a summary of the views of what came to be known as the MIT school of computational neuroscience, as it is a personal credo and a list of achievements of the second part of Marr's scientific endeavor, which lasted from about 1972 to 1980.

Legacy

The blend of insight, mathematical rigor, and deep knowledge of neurobiology that characterizes Marr's work is reminiscent of the style of such titans of neuroscience as Warren McCulloch – except that McCulloch's most lasting results were produced in collaboration with a mathematician (Walter Pitts), whereas Marr did his own mathematics. A decade after his quest was cut short, it has been claimed both that Marr is cited more than he is understood (Willshaw and

Buckingham, 1990), and that his influence permeates theoretical neurobiology more than what one would guess from counting citations (McNaughton, 1990). Still, contributors to the mainstream journals in neurobiology now routinely refer to the 'computations' carried out by the brain, and the most exciting developments are those prompted or accompanied by computational theories and models.

In computer vision (a branch of artificial intelligence), the influence of Marr's ideas has been complicated by the dominance of the top-down interpretation of his methodology: proceeding from a notion of what needs to be done toward the possible solutions. For some time, Marr's school was identified with the adherents of a particular computational theory of vision, which claims that constructing an internal model of the world is a prerequisite for carrying out any visual task. The accumulation of findings to the contrary in neurobiology and in the behavioral sciences gradually brought to the fore the possibility that vision does not require geometric reconstruction. This encouraged researchers to seek alternative theories, some of which employ concepts and techniques that did not exist in the 1970s, or were not known to the scholars of vision at the time. These new ideas, in turn, are making their way into neuroscience, as envisaged by Marr. Interestingly, many such ideas complete a conceptual circle by reconnecting with Marr's own earlier work represented by the trio of papers summarizing his dissertation. Thus, the machine-learning approaches that have become indispensable in modeling cognition can be seen as related to the probabilistic methods invoked by Marr in connection with codon-based statistical learning and inference that he developed.

On a more general level, Marr's work provided a solid proof that a good theory in behavior and brain sciences need not have to trade-off mathematical rigor for faithfulness to specific findings. More importantly, it emphasized the role of explanation over and above mere curve-fitting, making it legitimate to ask *why* a particular brain process is taking place, and not merely what differential equation can describe it or what the neural circuit implementing it looks like.

Abstract

Marriage as a central framing device within anthropological theory has proved illusory because of the lack of a universal definitional basis on which to peg its significance. This article seeks to explore how marriage, as an anthropological object, has transformed through time alongside important changes within anthropology and especially with regards the anthropological study of kinship. It argues that marriage cannot be plausibly isolated from other social institutions and explores it as a web of meaning and effects that are open to anthropological interpretation.

Since the late nineteenth century, marriage in its ritual and regulative forms has come to be seen as a crucial aspect of the subject that anthropologists regard as most traditionally close to their hearts: the study of kinship (Morgan, 1997[1870]). Marriage has certainly been recognized as central in understanding bonds of kinship, for exploring the nature of these bonds and their effects upon the persons participating within relations effected by marriage and for expressing exchange, intimacy, sociality, and care. However, marriage as a central framing device within anthropological theory has proved illusory because of the lack of a universal definitional basis on which to peg its significance (though, from a postmodern perspective, we can probably reassure ourselves that this need not be desirable nor indeed, may it serve as the deformity it was often made out to be). Rivière, for instance, has argued successfully that 'marriage' cannot be treated as an isolable phenomena (1971), and Strathern has extended this caution in an ethnographically detailed account that serves to challenge what the subject matter of marriage, and marriage exchanges might be (1984). This historic complexity notwithstanding, globally and popularly, marriage continues to be thought of as a socially approved union that links sexual access to rules concerning the care, legitimacy, and social affiliation of children. Underpinning this popular (nonanthropological) consensus about what 'marriage' is about, is the noticeable presence in contemporary Western states of online and actual world 'marriage publics' who rally around particular conceptions of marriage as natural/cultural; or a 'universal human right' or defined as the 'right to found a family' (Borneman, 1996: p. 216). Marriage, as an anthropological object, thus sits at an interesting confluence of kinship studies (including those of gender, intimacy, commodification, and migration), politics and religion, and the study of legal anthropology that seeks to critique and understand the meanings, contexts, exchanges, and relationships that attach and make manifest 'rights.' Despite the approach of this article that explores the place of marriage within kinship theory, one could certainly argue with Leach that marriage cannot be plausibly separated out from other social institutions (1961) but that it forms an inextricable web of meaning and effects that are open to anthropological interpretation.

Definition of Marriage

The 1951 Edition of the Royal Anthropological Institute's 'Notes and Queries' defined marriage in the following way: "Marriage is a union between a man and a woman such that children born to the woman are recognized legitimate offspring of both parents" (1951: p. 110). Subsequent attempts along these lines to delineate a cross-culturally valid definition of the rights and responsibilities that constitute marriage (for example, defined as conferring rights to sexual access of women) have similarly come to grief (see Comments section following Bell, 1997). As we can see, older anthropological texts were not chary of declaring marriage to be about heterosexual unions (monogamous or polygamous), bearing offspring to swell the family and lineage. Ten years later, the British anthropologist Edmund Leach took a much more capacious view of marriage defining it as 'a bundle of rights,' which might include 'several distinguishable subtypes of institution' such as those that establish legal parenthood (fatherhood/motherhood), monopolize the spouse's sexuality, generate rights in the spouse's labour and property, establish a fund to care for offspring to the marriage, and/or establish a socially significant relation of affinity and 'possibly many more similar rights' (1961). The crucial aspect here is that no single set of rights or roles were regarded as central to a universal definition of marriage, because Leach did not consider such a universal definition of marriage to be viable. Leach's definition hinged upon legality and legitimacy, but nevertheless chimed with those like Needham who urged that 'marriage' as an analytic device be treated as an 'odd-job word' more likely to mislead rather than yield cross-cultural comparison, and worse still, of 'no use at all in analysis' (1971: pp. 7–8). In some ways, anthropological definitions of marriage were either driven by its ritual significance (e.g., 'marriage by capture,' 'group marriage,' 'polygynous marriage,' see for instance McLennan, 2012[1865]) or its regulative importance (marriage as a rite conferring legal rights) with little consideration of how people actually experienced the processes of marrying and making kin.

In recent years, feminist anthropologists and queer theorists have critiqued anthropological studies of marriage (most obviously, Levi-Strauss' ambitious volume *The Elementary*

Structures of Kinship) by reminding us that it is by no means obvious, natural, or universal that marriage involves a heterosexual couple, the exchange of wives by groups of men, nor indeed should we assume marriage to be the principle regulative force or loci of kinship solidarity and care (Rubin, 1975; Borneman, 2001). However, the critique of the cross-cultural variability through which marriage manifests itself was already widely in evidence. Evans-Pritchard had argued that the institution of 'woman marriage' showed that fatherhood among the Nuer was a status conferred to the person in whose name cattle bridewealth was given for the mother; so in this sense, a woman could be both a husband and the father to her wife's child if cattle were given in her name (1951: p. 107). Evans-Pritchard's account of boy-marriage among Azande warriors and *bagburu* lesbian 'friendships' among Zande women in polygamous marriages demonstrated the institutional marital forms of 'libidinous plasticity' that dealt with situations of shortage of heterosexual partners through same-sex relations that were crucially, he argued, *called* marriage (1970). The present attempts to legitimate and legislate for same-sex marriage in many parts of Euro-America, seek to institutionalize nonheterosexual marriages through legal means. Indeed, as Kath Weston has argued in her ground-breaking ethnography of gay and lesbian kinship in California (1997), the conflation of kinship with ties of biology and the consanguineous family has, in recent decades, depleted our anthropological imagination of the multitudinous ways in which kinship itself is made and *not* given (Weston, 1991), even if anthropologists have observed that this (re)making is surprisingly often along normative lines (Bonaccorso, 2009).

Marriage and Kinship

Over half a century ago, marriage and reproduction through parenthood (and sibblingship) were seen as centrally constitutive of kinship. The 'elementary family' of Radcliffe-Brown (1952), imagined to be constituted by two parents and their children were seen to constitute the proper subject of study that we call kinship, though as Bohannan subsequently argued, the matricentric family (constituted of a woman and her children) was far more "universal and more elementary than the nuclear family" (Bohannan, 1963: p. 73).

Marriage, in this schema was designated by the kinship outcome of 'affinity' with affines being the persons to whom one was related through marriage. We should note here an interesting point raised by the French anthropologist Dumont in his appraisal of the role of marriage in two competing anthropological theories of kinship: that of descent (whose proponents were of the British structural-functionalist school) and alliance (whose proponent was the French Structuralist Levi-Strauss). When we refer in English to the kinship ties of blood and marriage, we use the words 'relations of kinship *and* affinity' because the term kinship is broadly understood to be based on consanguineous ties. By contrast, in French the word *parenté* encompasses *both* consanguinity (relations of shared blood), and affinity (relations by alliance or marriage). Consequently, to demonstrate the importance of marriage to a study of kinship, anthropologists writing in English were self-consciously using the words kinship and affinity (to designate ties of blood and marriage) whereas the French *parenté* sufficed for both. Dumont argued from all this that the peripheral place of marriage in British Structural-functionalists descent theory, and its centrality to alliance theory among French Structuralists, may in fact be related to the linguistic peculiarity that requires an elaboration to the term 'kinship' to be paired with 'affinity' in English and that encompasses ties of blood and affinity through the word *parenté* in French (2006 [1971]: p. 3). In descent theory, descent groups import women to reproduce the group (through reproduction). The function of marriage is to perpetuate the lineage system and marriages between groups preclude further marriages for some generations. In alliance theory, the exogamic groups were ordered to organize marriage and one marriage generates a systemic alliance between groups – the marriage tie being a structural element in the system of alliance and reciprocity on a wider social scale. 'Marriage alliance' refers to the repetition of intermarriage between larger or smaller groups, typically descent groups. The concept of marriage alliance was developed by Levi-Strauss to deal with societies that practice various forms of cross-cousin marriages. He argued that such repeated exchange of women (by men) through marriage created ties of mutual interdependence among groups; marriage was a quintessential system of exchange.

The reciprocity and exchange that drives alliance theory were argued by feminist anthropologists to be "reckoned in female flesh" (Rubin, 1975: p. 182). Gayle Rubin pointed out that both British Structural-functionalism and French Structuralism were united in their uncritical view of the rules of gender division between male and female, and the 'obligatory heterosexuality' that ensued from both theories of marriage and consequently, that came to dominate the study of kinship (1975: p. 182). Anthropologists have gone to great lengths to identify the ways in which marital choice is constrained (through the veritable universality of some form or the other of the incest taboo as well as through a range of kinship practices that enjoin marriage in one direction and restrain it in others). It is also clear that in many societies, a high degree of constraint in terms of marital choice may frequently coexist with a relatively acquiescent attitude to premarital and extramarital sex (see Evans-Pritchard, 1951; Gell, 1996; Boellstorff, 2005). In this vein, while lauding the work of feminist anthropologists in their critique of biological/genealogical determinism in kinship studies (the idea that "kinship includes large universes of people whose relatedness may or may not have anything to do with notions of blood"), Bodenhorn argues that the study of marriage and kinship needs to be much more attentive to the 'instability' of categories such as race (2013). Given its alliance potential, marriage has always served as exemplary in its 'transboundary capacities,' and Bodenhorn draws attention to the ways in which the modern invention of categories such as 'race' and 'ethnicity' make 'intermarriage' a marked (rather than an unmarked) relationship (2013: pp. 132–133). This marking has a peculiarly 'muting effect' on the many crossings that have always served as a widespread basis for marriage and making kinship.

Marital Gifts

Anthropologists have frequently regarded marriage in so-called 'traditional' societies as an exchange between two communities rather than between two individuals, and consequently it is a public social event that has the potential to alter the relationship, property, and status between those two groups. From a structuralist perspective, marriage payments 'are conceived as elements within total exchange systems' and they are not considered interesting independent objects of investigation (Comaroff, 1980: p. 30). So while the act of a marriage is expressed in a ritual or a ceremony, it invariably also transfers 'goods, rights, and people'; with the end of marriages marked by the relocation of these (Simpson, 1994: p. 832). Two of the 'classic' forms of presentation given at marriage are called bridewealth and dowry and the difference between the two are characterized by the direction taken by the flow of gifts. Dowry is the name given to property passing in principle from the bride's parents to the bride, though it is often the case that the dowry goes directly to the bride's in-laws. Bridewealth on the other hand is property that goes from the groom or the kin of the groom to the kin of the bride. Among the Nuer, for instance, the exchange of bridewealth from groom's kin to bride's kin in the form of cattle serves to secure paternity for any children born to the marriage of the man in whose name the cattle had been given. They are, as Evans-Pritchard argued, "the children of the cattle" (1951: p. 98). The anthropological commonplace that bridewealth flows in 'the opposite direction of the bride,' while dowry moves with her conceals a number of interesting assumptions about the nature of marriage, not least that women move in true Levi-Straussian fashion between male kin and that their movements can be juxtaposed against the movement of marital gifts between these kin. Gift giving at marriage is a vitally important kinship-based economic activity and in the past, in China for instance, assembly of the wealth necessary for generating bridewealth could tie up the economic activities of household members for decades at a time (Yan, 2005). Osella and Osella provide a detailed exploration of a shift among Izhavas in Kerala from low-status 'poor people's' cross-cousin alliances toward hypergamous unions (preferably to Gulf-employed grooms) that are set apart by high prestige payments of large dowries that transform dowry into "groom price" (2000: pp. 81–116). Significantly, among Mawri men in Dogondoutchi, a Muslim Hausa-speaking town in Niger, Africa, 'nonmarriage [was] not an option' and young men felt an enormous pressure to demonstrate their marital eligibility through assembling suitable amounts of bridewealth or *sadaki* in order to find a wife (Masquelier, 2005: p. 59). Men unable to acquire suitable *sadaki* were accused of being idle (literally, staying in the room or *daki*) and unable to 'forge a productive masculinity through proper marriage.' Masquelier argues that in Dogondoutchi, "[t]o win a young girl's heart, a boy had to ply her with costly fripperies" (1995: p. 74). Marital gift giving can also be seen as a "serial form of family division" (Yan, 2005) wherein economic wealth is distributed successively depending on the gender of the child who has married and the prevailing traditions of gift giving. However, anthropologists have been slow to investigate the full complexity and transformation of marital gifts as they often change with new economic circumstances and constraints, coalesce or get distributed throughout the life of the couple. Notably, Yan describes such a process in Xiajia, a village in rural China, where he witnessed a process in which three separate categories of marital gifts were converted into *ganzhe* (cash) and eventually into *daganzhe* ('grand conversion'), a unified category of bridewealth that was demanded directly by the bride. Marital gifts in terms of land or houses can therefore serve as a significant productive base for a couple and can be a valued 'conjugal fund' that they may draw upon over the course of their lives together.

Marriage, Roles, and Change

An increasing interest in intimacy and the nature of marital relationships has drawn attention to the ways in which earlier anthropological theories viewed consent in marriage. This was broadly viewed as a correlate of social forms so that high degrees of parental control over spouse selection indicated that the society as a whole valued lineal solidarity (with marriage the key functional mechanism for ensuring this). As Winch argues, in societies that value the extended family system: "Marriage will … be considered as the focus of the process of family formation, and mate selection as one of its most problematic features" (1968: p. 1). The evolutionist argument proceeds to assume that with changing family forms and greater nuclearization and gender equality, family members allow the couple greater choice and, left to generate their own marital criteria, the young and the nubile seek out partners with whom they share an attraction, romance, or love (Winch, 1968; Giddens, 1992). However, Robbins provides a fascinating counterpoint with ethnographic contextualization of the place of the 'nakedly spoken will' ('calling the name') for women instigating their own marriages among the Urapmin of Papua New Guinea (2004).

A rather different, and pioneering thesis on the roles of men and women *within* marriages came from Elizabeth Bott's network analysis of 20 working-class London families, focusing on the extent to which husbands and wives segregated their lives and roles from each other. Bott showed that differences in terms of roles (i.e., 'reciprocally expected behavior') between heterosexual couples depended strongly on "patterns of social relationships with and among persons *outside* the family" (1957: p. 219). The thesis of the study was that the social world to which an urban family was related was often quite dispersed. This was in contrast to close-knit communities where a family interacts with individuals who are themselves in close contact with each other and this generates shared norms and expectations about marital roles. Consequently, the more dispersed the social network of a family, the more impaired the couple's ability to look outside the marriage for help and support, thus reducing the exercise of external normative pressures upon the couple who are forced to be more self-reliant. Bott argued, "… if husband and wife come to marriage with loose-knit networks, or if their networks become loose-knit after marriage, they must seek in each other some of the emotional satisfaction and help with familial tasks that couples in close-knit networks can get from outsiders. Joint organisation becomes more necessary for the success of the

family as an enterprise" (1957: p. 218). Bott's network analysis showed that conjugal roles were less marked when conjugal interdependence was an emotional and social necessity. While this work never did become central to the anthropology of marriage, it was pioneering in network analysis and demonstrates the potential for innovation in thinking about the role of marriage within changing social structures.

In the same measure by which studies of marriage in the mid- to late-twentieth century came under fire for placing an undue emphasis on the structural rules and constraints of marriage viewed from the perspectives of corporate groups, more recent anthropological work has sought to explore the cultural contexts in which parental marital arrangement, self-choosing, and constraint express themselves through processes of marriage making (de Munck, 1996; Ahearn, 2001; Hart, 2007; Mody, 2008; Fuller and Narasimhan, 2008). This emphasis on the processual and agentive aspects of marriage mark the emergence of new possibilities for anthropological studies, promising to restore marriage to the forefront of kinship theory. The emphasis on the agency and choice of individuals (acting as such) in marriage is also stressed by the Sociologist Giddens in his work *The Transformations of Intimacy* (1992). Giddens characterizes shifts in conjugal intimacy as an outcome of a veritable global movement in which the so-called 'democratization of society' is accompanied by a concomitant stress on the equality between men and women, of the need for personal fulfillment in marriage and on the increasing recognition that when these needs are no longer fulfilled, then the marriages dissolve and end in divorce.

Marriage and the Creative Potential of Divorce

A more nuanced and historical view of marriage comes from Pat Thane who argued that premarital intimacy has been a feature of the courtship practices of large swathes of the population since at least the mid-eighteenth century in Britain, and that a similar picture emerges on high rates of nonmarriage among men and women bringing up children in the same time period; Thane argues that the period 1945–70 is exceptional in its regard for marriage and conjugal togetherness rather than the norm (Thane, 2010). In the context of discourses on freedom and enterprise in Euro-American life, Strathern has argued that the enterprise culture heralds 'enterprising kinship' in which the possibilities of expanded personal choice (not least in marriage) play a significant role in transforming intimate, kinship, and caring relationships (Strathern, 1992). Indeed, the anthropologist Bob Simpson has argued that concomitant effects of the ubiquity of divorce and remarriage in contemporary (Euro-American) society is a 'distinctive weft which runs through the fabric of society' connecting households, children, and property in new and complex kinship relations (1994: p. 832). Decoupling in the form of divorce (the legal mechanism sanctioning separation), is accompanied by new couplings and relationships legitimated in marriage, and Simpson argues that the resultant 'unclear family' (as juxtaposed to the nuclear family) allows us to refocus our anthropological gaze upon the creative possibilities of divorce to restructure and reorder interpersonal kinship and economic relations.

The anthropologist Jonathan Parry takes to task the Giddensian theory that an increasing stress on equality and conjugal intimacy *necessarily* leads to higher divorce rates by drawing on his detailed ethnographic study of low-caste Satnamis (descendents of Chamar untouchable converts) in Chhattisgarh (central India). Following Leach, Parry is careful to distinguish between jural and conjugal stability; he argues that people can remain married to each other even if they haven't seen each other for years. Parry argues that while the general image of caste society is one of jural stability in terms of very low divorce rates, customary forms of divorce and remarriage are common at the lower end of the caste hierarchy and among *adivasi* or tribal groups in India. For instance, among the Girasias of Rajasthan, 50% of household heads had been previously married at least once (Unnithan-Kumar, 1997). Questioning the unremitting stereotype about the stability of Indian arranged marriages with his own ethnographic material, Parry argues that "Certain pockets of the country sustain divorce rates quite comparable to contemporary California" (2001: p. 786).

Parry found that marriages among his older Satnami informants were much more fluid than caste-Hindu marriages, and that almost half of all Satnami primary marriages had been terminated by divorce. By high caste-standards, Chhattisgarhi women were immodest; as one of Parry's female informants told him: "a new husband keeps a woman feeling young. Only when she gets old and tired that she settles for what she has got." Satnami women working as laborers commonly embarked upon trysts and elaborate extramarital affairs where commonplace and widespread. What Parry found was that among the younger generation of Satnamis, there was a genuine shift in values away from the free and easy marital ways of their parental generation. In general (and contrary to expectations) Parry found that his younger Satnami informants had a lower rate of divorce than the over-45s. This squared with his findings that among a certain segment of the working class who had availed the benefits of public sector (stable) employment in the Bhilai Steel Plant where many of Parry's informants worked, the figure for divorce in the same age cohort was even lower. In other words, the younger generation, particularly those in more stable forms of employment were rejecting the older styles of casual marriage, divorce, and remarriage punctuated by freer sexual couplings at all stages and were thus keen to emphasize the *indissolubility* of their marital bonds (2001: p. 817). As Parry saw it, the trend for younger Satnamis was away from the systematic (or 'cold-brained' as his informants put it) intimacies and romances accompanying high rates of divorce toward marriages that in Parry's words were more stable and carried a much heavier "emotional freight" (2001: p. 816). Parry's further insight was that the stability of these marriages came at an ideological cost – young Satnami women were far less likely to go out to work, and their increasing domestication as housewives undoubtedly limited their sexual opportunities as well as increasing their economic dependency upon their husbands. The economic (and sexual) independence of their

mothers' generation was thus traded for an emotionally secure, but economically unequal notion of marriage.

Marriage and Love

Parry's argument about marriage and divorce for younger Satnamis in Chhattisgarh runs contrary to Gidden's idea that the increasing prevalence of 'love' as a motive for marriage is tied to economic independence, and that it allows couples to break free from the kinship and familial obligations (and economic dependencies) they might have sustained in the past (see de Munck, 1996). An outcome of the resulting interest in marriage as a process has been an attention to forms of intimacy and love as socially derived. The anthropologist de Munck found that love was a 'deep motivation' for his Muslim informants in the Tamil Sri Lankan village of Kutali, but interestingly, he argued that it was utterly compatible with and indeed, helped to sustain arranged marriages between cross-cousins; thus love was a factor that was serving to perpetuate a particular kinship form of marriage that has been fast disappearing the world over (Fuller and Narasimhan, 2008). Marriages in Kutali were mediated by family members, with *marikars* (mosque officials) playing a central role in helping negotiate the appropriate dowry to be paid. Dowry in this agrarian community always included a house, some paddy land, and some money. 'Love' played no part in the dowry negotiations and the bride and groom were 'publicly backgrounded,' and expected to appear submissive to the authority of the elders, even when the marriage was known to be the outcome of a love affair that had come to light. When such affairs were discovered, the *marikars* sought to 'punish' the couple by invoking Islamic law or (Shari'a) and pressuring both families to agree to a marriage.

What is interesting in de Munck's work is the way in which he shows how love in Kutali has evolved in such a way that it is almost directed toward the most appropriate spouse, one's cross-cousin. So, for instance, boys in the village explained that it was embarrassing to bathe in the river in front of one's 'sister' (real or classificatory) but pleasurable to bathe with a female cross-cousin or *mathini* (1996: p. 708). Furthermore, male circumcision rites provided an 'institutionalized setting' for cross-cousins to recognize themselves as potential marital partners, with their *mathinis* (female cross-cousins) expected to visit them at home as they recuperated and enquire after their health with gifts of sweets.

The sweets were known as *kaum*, a slang word for vagina. Thus, the giving of *kaum* and the enquiry into the health of the 'friend' was interpreted by de Munck as a form of 'institutionalized foreplay.' De Munck says, "The absence of sanctions against public interaction between opposite-sex cross-cousins and the obvious intent of the post-circumcision visits help direct the course of romantic love toward someone from the culturally approved social category" (1996: p. 708). Of 18 newlywed couples that he worked with, 14 declared that they had *anpu* (love) before marriage was discussed, and of these, 10 love marriages were between individuals related as cross-cousins (1996: p. 709). Thus love served as a vital means through which the social structure was maintained and through which the flow of love and sexual desire was directed. In a different vein, my own work (Mody, 2008) with love-marriage couples in Delhi (India) showed that when couples' love became publicized they were frequently forced to inhabit a space of 'not-community,' beyond the pale of social relations and meaningful kinship connections and economic support. Consequently, maximum effort was expended to try and keep romantic 'love' from sight, working on the premise that given time (not infrequently, many years) of dutiful and loving kinship love and care, intransigent parents would eventually come around and agree to arrange a marriage of their children to each other. Here, what was sought was parental consent and its stamp of approval upon a visibly arranged marriage, and it was this flow of public marital legitimacy (concealing private love) that was powerfully deployed to domesticate love marriages in urban India. Given the centrality of consent in current debates about marriage (for instance, 'child marriage,' 'forced marriage') and the ways in which people can be characterized as objects (for example, in discourses on trafficking) or "subjects willingly agreeing to be objects" (Van Baal in Strathern, 1984), marriage continues to provoke profound anthropological questions on transnational migration, kinship, reciprocity, gender and sexuality to ethics, self-making, and care.

Marriage and the Dual-Career Family

This article is a revision of the previous edition article by L.J. Waite, volume 14, pp. 9261–9265, © 2001, Elsevier Ltd.

Abstract

Marriage and dual-career families are two aspects of work and family that have changed dramatically over the past half century. In addition to the changing definition of marriage, there have also been shifts in the timing and stability of marriages since midcentury. Expectations associated with the roles of wives and husbands have also shifted to make way for the dual-earner family where both spouses are employed in market work. Dual-career families are those where both partners are pursuing careers, typically full time and often with children. This article will explore the changes and implications associated with both marriage and dual-career families.

Changes in Marriage

The legal definition of marriage as well as the rights and benefits associated with marriage have been a source of debate over the past few decades in the United States and other Western nations. Marriage has historically been defined as both a legal and religious union between a man and a woman. The Civil Rights Movement in the 1960s ultimately led to the legalization of interracial marriage and contemporary debates about marriage have focused on whether same-sex couples should be granted the right to marry. Recently, some Western countries have begun to legalize same-sex marriages, including some states in the United States. As these debates progress, the attitudes toward marriage have generally gotten more liberal. Internationally, the acceptance of homosexuality is most pervasive in more secular countries (Pew Research Center, 2013).

The primary reason why the conflicts over who is allowed to marry are so intense is because the legal, social, and economic benefits of marriage are numerous. Proponents of same-sex marriage argue, for example, that there are over 1000 benefits to marriage not available to single people or people in civil unions (an alternative to marriages offered to same-sex couples in many states). Further, some scholars and policy makers argue that marriage offers so many benefits to its members that marriage should be encouraged through policy. Some of the more obvious benefits to marriage include the ability of partners to specialize, pool risk in the case of economic shortfall (in the case of dual-earning spouses), and companionship. Detailed comparisons of married individuals to never married, widowed, divorced, and cohabiting individuals has yielded further insights into how marriage results in greater earnings, wealth health, life span, and even sexual satisfaction for those who marry (Waite, 1995).

Other scholars note that the so-called benefits to marriage are actually selection effects. Those who are the healthiest and have the most earning potential are more desirable marriage mates and thus more likely to enter into marriage. Further, whatever benefits that may arise from marriage itself, and not simply from selection effects, are bestowed unevenly to men and women, with men gaining marginally more from marriage than women. These scholars also argue that policies aimed at promoting marriage – particularly to low-income populations who are less likely to marry – are problematic because research on low-income individuals, particularly single parents, does not show that these individuals do not want to marry or are not aware of the benefits that may be associated with marriage. On the contrary, most people with low income aspire to get married but feel constrained by limited job opportunities and financial instability. They understand that economic stress strains relationships and do not want their marriages to end in divorce (Edin and Kefalas, 2005). As a result, some have concluded that if societies are concerned about marriage rates because they deem marriage desirable then policies should focus on improving the economic infrastructure of communities with low marriage rates if they are to be successful (or happen at all).

Marriage rates, in fact, are at an all-time low in recorded history in the United States at 31.1 – roughly 31 marriages per 1000 unmarried women. Marriage rates were high at midcentury (90.2) when 65% of women aged 15 years and over were married (Cruz, 2013). Still, most people marry or aspire to marry in the United States. Sixty-one percent of those who were not married would like to be someday and the husband–wife household is still the most common type of family household.

Marriage rates have declined partly because of the large shifts in the timing and stability of marriage. The extent to which the timing of marriage has changed over time, however, depends on the starting point of the analysis. If the starting point is the beginning of the twentieth century, then it would seem as if there is only a slight increase in the timing of the first marriage, but if the starting point is midcentury, the shifts appear more dramatic. Median age at first marriage in 1890 was 26.5 years for men and 23.6 years for women compared with 24.0 for men and 20.5 for women in 1950. Only by the 1990s did the median age at first marriage for men and women approach the 1890 levels (Elliott et al., 2012). Since the 1990s, the median age at marriage has continued to increase. In the United States, it is now in the late twenties (approaching age 30 years for men), and over age 30 years in some Western European countries. The continued increase in women's and men's median age at first marriage beyond the turn-of-century levels is likely connected to women's pursuit of educational and careers opportunities not available to them in earlier generations as well as expectations that women be economically independent from men (Martin, 2004). This is partially reflected in the higher age at first marriage among college-educated and post-college educated men and women.

Trends in marriage rates also vary widely by race. Rates are significantly lower among blacks such that about approximately a quarter of black men and women over the age of 35 years have never been married relative to roughly 10% of whites (Elliott et al., 2012). From the beginning of the twentieth century through midcentury, black men and women were getting married at younger ages than white men and women, respectively. By 1950, the median age at marriage for whites and blacks converged and the median age at first marriage for black women and men began to rise above the ages for whites in the decades that followed. At present, the median age at first marriage for black women is around 30.0 years compared with 26.4 years for white women and 30.7 for black men compared with 27.8 years for white men, reflecting a smaller gender disparity in age at first marriage for blacks than white (Elliott et al., 2012).

Cohabitation

While marriage rates have declined, cohabitation rates have increased. It is tempting to assume that cohabitation has become a substitute for marriage, but cohabitation in the United States is more aptly characterized as a precursor to marriage, although cohabitating unions are increasingly diverse and complex. Still, most marriages in the United States are preceded by cohabitation and there are only a handful of countries where the civil benefits associated with cohabitation rival marriage, and thus cohabitation has become a substitute for marriage.

Individuals may also cohabit in the wake of a divorce. Although divorce rates have stabilized since the 1980s, they are still relatively high in most Western nations with the United States and Eastern European countries having some of the highest rates in the world. Comparatively, rates were lower in places like Libya and Mongolia. Data on remarriages is limited, but evidence suggests that most people who get divorced in the United States get remarried, indicating that marriage is still a popular institution. Still, remarriage rates – like marriage rates – have declined (Sweeney, 2010).

Declining marriage rates have led some to question the extent to which marriage is still a powerful institution, and moreover, whether it has undergone a process of deinstitutionalization, meaning the expectations and norms associated with marriage have weakened or become unclear (Burgess and Locke, 1945; Cherlin, 2004). Marriage as a status symbol is still very strong, but what it means to be married is more complicated and varied than in previous generations. Cherlin (2004) argues that marriages moved from being institutional to companionate to ultimately individualized marriages emphasizing personal development, emotional satisfaction, and flexible roles rather than simply sacrificing for one's partner.

Increases in Women's Employment

It is difficult to say whether the changing norms associated with marriage are a result of changing behavior or changing behaviors resulted in changing norms, but women's increased employment and career aspirations are often noted as an explanation for delayed marriage, nonmarriage, and even divorce. The explanation is that women's increased employment leads to greater economic independence and thus reduced economic benefits to marriage (Becker, 1981; McLanahan and Casper, 1995). High rates of women's employment also make singlehood more attractive to women and divorce more feasible options, as women are less financially dependent on men. Changing norms seem to be an incomplete explanation for delayed marriage, however, given that women with attractive economic resources are not the least likely to marry and, in fact, may be more likely to marry (Oppenheimer and Lew, 1995). The period of rising employment has also been marked by slight declines in the earnings of men, particularly young men, which makes marriage less economically attractive for women (Oppenheimer, 1994).

Since the first half of the twentieth century, a period when married women faced discriminatory attitudes and policies limiting their employment opportunities, women's employment has increased steadily, particularly among married women and married mothers (Goldin, 1990). In 1978, 56% of all women aged 25–54 years were employed and this increased to 71% in 1998, or a 15.5% increase. When the universe is restricted to married women, there was an increase of 17.4% between 1978 when employment rates were 51.4% for all married women and 68.8% in 1998. The largest increase at 20.1% was observed for married mothers with preschool-aged children between 1978 and 1998 when rates rose from 38.1% employed to 58.2%. Even though most women were employed by the end of the 1990s, including most married women and most mothers with young children, rates of full-time employment (especially full-time, year-round employment) were much lower, at about half of all women and roughly a third of married mothers with children under age 6 years (Cohen and Bianchi, 1999). Trends in married women's employment rose to some of the highest levels in countries like Sweden where the rates ranged between 80 and 90% (Spain and Bianchi, 1996). These shifts in women's employment – particularly married women's employment – were so sweeping across most Western nations that they are best described as a revolution with few if any signs of reversing.

Division of Labor inside the Home

The movement away from the male breadwinner–female homemaker model to the dual-earner model from the 1970s to present was swift. In 1970, close to 90% of couples had conventional work–family arrangements where the husband was the sole or primary provider. By 2001, most (64%) couples still followed conventional earning arrangements where husbands were still the sole or major provider, but those where wives shared equally in providing income made up nearly a quarter of couples and couples where wives were primary or sole earners were 12% of all couples (Raley et al., 2006). Although the shift was less striking among working class and minority families, who had higher employment rates than middle class and white families in earlier eras, a similar pattern was observed (Bianchi, 1981).

As married women, especially mothers, became part of the labor force, sweeping changes were happening with work inside the home as well. Given that women were now spending

substantially more time in market work than previous generations, and that time is finite, employed women had to reduce the time they devoted to nonmarket work. In fact, the increase in time spent in market work is mostly accounted for by a reduction in time spent in housework (Bianchi, 2000). The reduction in time spent in housework is one that is observed among both employed and unemployed women, perhaps reflecting a decreased emphasis on spotless houses, the increase in time-saving devices to increase efficiency of completing household tasks, or the ability to outsource household tasks.

The gendered division of labor in the home – particularly in terms of housework – receives a lot of attention from scholars because it is seen as an indicator of gender equity to examine how much men and women in dual-career couples share in the additional unpaid work required to maintain a household. Time use studies of housework show that the reduction in housework among wives during the period of rising women's employment cannot be explained by a comparable increase in housework among married men, although married men's housework has steadily increased since the 1960s. Men's household contributions are still lower than women's, but they are closer than they were in the past largely due to declines in women's time rather than increases in men's time (Raley et al., 2012). There are a number of factors that seem to be associated with the proportion of housework that husbands do. For example, husbands' hours increase as they spend fewer hours in the labor market, as their wives spend more time in the labor market, and when they have more gender egalitarian attitudes (Coltrane, 1996).

The Second Shift: Strains of Dual-Career Families with Children

The dramatic increase in married mothers' movement into the labor force between the 1960s and 1970s sparked alarm that mothers were reducing their time with children to accommodate their time spent working outside the home. Fears of neglected, 'latchkey' children who were harmed by too many hours in day care and not enough time with their mother abounded. Yet, careful studies of parents' time use over the period of rising maternal employment (1960–90) suggested that time with children remained stable (Bianchi, 2000; Bianchi et al., 2006).

As employed married mothers stretched their schedules to make sure children were getting the time and attention they need, concern arose that mothers were carrying an unequal burden of the household maintenance compared to their husbands. Arlie Hochschild (1989) coined the term 'second shift' to describe the additional shift of housework and child care that mothers employed full time with young children worked after completing their first shift of market work. In her landmark qualitative study, Hochschild (1989) found that the men in these households did not work a lengthy second shift and that their contributions to the daily management of the household were marginal compared to what their wives did. Further, the men often overestimated their contributions or thought they were more equal than they actually were. Both the husbands and wives in these couples reported marital strain, sleep deprivation, and extreme feelings of time pressure, although feelings were more acute for women than for men.

Subsequent examinations of the total workloads (family work + market work) of men and women in dual-earner couples have found women's workloads to be slightly higher or similar to men (Bianchi et al., 2006; Milkie et al., 2009). Although women do far more nonmarket work than men on average, men tend to spend more time in the labor market, even when both members of the couple are employed full time. Gender disparities are larger for dual-earner couples with children, and these disparities are largest when both partners work full time and have preschool-aged children (Milkie et al., 2009). This population of mothers experiences the largest 'second shift,' and also feels extreme time pressures trying to do it all. Although they do not appear to get much less sleep than their spouses or compared with mothers in other family types, they experience less leisure than their husbands and mothers in other types of households.

Time Pressure and Total Hours of Family Work
